

Idaho Water Supply Outlook Report June 1, 2009

Mores Creek Summit SNOTEL

This picture of the Mores Creek Summit SNOTEL, located north of Idaho City in the Boise Basin, was taken on May 28th, 2009, and features the last remnants of the site's snowpack and the emergence of the snow pillows. The Mores Creek SNOTEL measured the peak snow water content (29.7 inches) on April 11th, 2009. It took over four months to accumulate the snow pack and 48 days to dwindle the site's snow water content to zero on May 29th, 2009. During that time, the average melt rate was 0.6 inches per day and the maximum melt rate exhibited just prior to melt-out was approximately 1.5 inches per day.

How forecasts are made

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation, antecedent streamflow, and indices of the El Niño / Southern Oscillation are used in computerized statistical and simulation models to prepare runoff forecasts. These forecasts are coordinated between hydrologists in the Natural Resources Conservation Service and the National Weather Service. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertain the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they may want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they may want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

The U.S. Department of Agriculture (USDA) prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex, marital status, familial status, parental status, religion, sexual orientation, genetic information, political beliefs, reprisal, or because all or a part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) Persons with disabilities who require alternative means for communication of program information (Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

To file a complaint of discrimination write to USDA, Director, Office of Civil Rights, 1400 Independence Avenue, S.W., Washington, D.C. 20250-9410 or call (800) 795-3272 (voice) or (202) 720-6382 (TDD). USDA is an equal opportunity provider and employer."

IDAHO WATER SUPPLY OUTLOOK REPORT

June 1, 2009

SUMMARY

Moderate temperatures and timely precipitation is turning the 2009 runoff season into a moderate year. May precipitation ranged from above average in the west-central and northern basins to about half of average in the Little Lost basin. June 1 snow levels range from melted out in many of the southern Idaho basins to almost average in the Clearwater basin. Residual streamflow forecasts for June-July are less than a month ago and range from 50-100% of average for most of the state. Overall, most reservoirs should fill; the exceptions are the reservoirs in central and across southern Idaho. Irrigation supplies may be tight for users in the Magic, Mackay, Little Lost, Salmon Falls, Oakley, and Bear Lake basins. Depending on the summer's irrigation demand, better carryover reservoir storage for next year is also favoring basins that had better carryover from last year; these include Dworshak, Payette, Boise and Upper Snake reservoirs.

SNOWPACK

The snow is running out. Current basins reporting no snow as percent of average at the snow measuring sites in their basins are Weiser, Little Wood, Big Lost, Oakley, Salmon Falls and Bruneau basins. The Clearwater basin has the highest snowpack at 92% percent of average. The June 1 snowpack in other basins is: 86% in Northern Panhandle, 78% in Spokane, 67% in Salmon, 74% in Snake above Palisades Reservoir, near 55% in Boise and Henrys Fork basins, and 69% in the Teton basin. Elsewhere the snowpack is less than 50% of average and will soon be melted. There is still snow present in the Idaho's higher elevations above many of the snow measuring stations which will help sustain flows into early summer. This is especially true in the Teton basin, where Grand Targhee SNOTEL site, elevation 9,260 feet, has 40 inches of snow water and 78 inches of snow on the ground. This site is currently losing about an inch of water a day and two inches in depth a day. Last year it melted out July 15 and should be melted before the end of June.

PRECIPITATION

Average or better May precipitation amounts fell in the region from the Big Wood basin to the west central mountains and north to the Canadian border. The South Fork Payette basin received the greatest May amount at 157% of average. The least amounts fell in the Little Lost and Mud Lake area at only 45% of average. Elsewhere, May precipitation amounts ranged from 70-85% of average across Idaho's southern basins, western Wyoming, Little Wood and Big Lost basins. Water year-to-date precipitation sounds encouraging with near average amounts and the biggest precipitation months behind us, but it does not always correlate one to one with streamflow. Average precipitation for the water year is good for the forests, dryland and rangelands, but the timing and intensity of rain will affect streamflow runoff in a positive or negative manner. The highest water year-to-date amounts are in Oakley, Salmon Falls and Bruneau basins at 108% of average. Lowest amounts are the Northern Panhandle Region and Weiser basin 86% of average. Elsewhere, amounts range from 91-104% of average. Additional spring moisture would improve the runoff in basins that still have snow to melt, and cooler summer temperatures will keep irrigation demand at moderate levels and may help reduce fire potential.

RESERVOIRS

Most reservoirs are in the 90% of capacity range and waiting for the inflows to subside for final fill of the reservoirs. The exceptions are reservoirs in central and southern Idaho that we have been talking about all season. Reservoir storage, from highest to lowest: Mackay is 86% full, Magic and Owyhee are 55% full, Oakley and Salmon Falls are 41% full and Bear Lake is 37%. The two major upper Snake reservoirs that are still waiting for additional runoff are Jackson Lake at 88% full and Palisades at 67% full. These reservoirs will fill physically based on the projected runoff, but additional moisture will help ensure the allocations for Jackson Lake and Palisades Reservoir also fill. May precipitation, was 85% of average in the Snake basin above Palisades and additional moisture in the first half of June would certainly help.

Note: NRCS reports reservoir information in terms of usable volumes, which includes both active, inactive and in some cases, dead storage. Other operators may report reservoir contents in different terms. For additional information, see the reservoir definitions in this report.

STREAMFLOW

The runoff this year can best be described as fairly controlled. Streams increased with warmer temperatures in mid-April and then decreased with cooler temperatures later in the month. The streams rebounded with warmer temperatures in mid-May only to level off at higher flow levels with moderate temperatures but the momentum of the melting snow was still present feeding the streams and maintaining the higher manageable flows. As a result, there were multiple peaks from the snowpack this year. A few streams, like the Teton River and Buffalo Fork in eastern Idaho and western Wyoming, have not peaked yet from this year's snowmelt. Streams in full recession are Owyhee, Salmon Falls, Goose Creek, Trapper Creek, Camas Creek near Blaine, and Weiser.

Residual streamflow forecasts for the June-September period are for near average in the Clearwater and Upper Snake basins. Streams across central and southern Idaho are forecast in the 45-75% of average range. While the Salmon basin and Panhandle Region streams are forecast at 80-90% of average.

Note: Forecasts published in this report are NRCS forecasts. NRCS uses timely SNOTEL data to provide streamflow forecasts. Jointly coordinated published forecasts by the USDA NRCS and the NOAA NWS are available from the joint west-wide Water Supply Outlook for the Western US at <http://www.wcc.nrcs.usda.gov/wsf/westwide.html>. The forecast numbers mentioned in this narrative are the volume under the 50% Chance of Exceeding, which means there is a 50% chance the volume will be greater or less than the given value. Water users may wish to use a lesser exceedance forecast to reduce the risk of coming up water short or greater volume to mitigate high flow potential.

RECREATION

Enjoy! The snowmelt runoff season is here! Moderate melt produced moderate streamflow peaks this year. The Bruneau River, in southern Idaho, is still receding and flowing at 1,000 cfs, as of early June. While Idaho's famous whitewater rivers in the Clearwater and Salmon basin have just peaked are just starting to recede to lower, fun family floating levels. Know your boating limits and boating confidence while the rivers are still high and additional rain can change the flows fairly rapidly due to saturated soils from the receding snowpack.

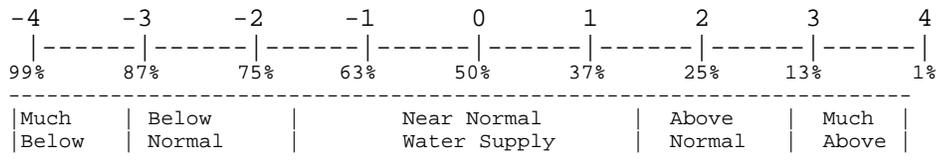

To provide guidance to water managers and river runners, there are a number of graphs on the Idaho NRCS Peak Streamflow Resources page: <http://www.id.nrcs.usda.gov/snow/watersupply/peakflow.html>. A number of these graphs illustrate the relationships between snow and streamflow peaks for Idaho's major basins. Similar snow years and historic flow exceedance levels are also included as references for this year's conditions. Projections are made periodically after the snowmelt peaks have occurred and streams are in recession. These graphs are manually updated once a week or more during the runoff season and less often in the summer months.

The Surface Water Supply Index (SWSI) is a predictive indicator of surface water availability within a watershed for the spring and summer water use season. The index is calculated by combining pre-runoff reservoir storage (carryover) with forecasts of spring and summer streamflow. SWSI values are scaled from +4.0 (abundant supply) to -4.0 (extremely dry), with a value of zero indicating a median water supply as compared to historical occurrences. The SWSI analysis period is from 1971 to present.

SWSI values provide a more comprehensive outlook of water availability by combining streamflow forecasts and reservoir storage where appropriate. The SWSI index allows comparison of water availability between basins for drought or flood severity analysis. Threshold SWSI values have been determined for some basins to indicate the potential for agricultural irrigation water shortages.

<i>BASIN or REGION</i>	<i>SWSI Value</i>	<i>Most Recent Year With Similar SWSI Value</i>	<i>Agricultural Water Supply Shortage May Occur When SWSI is Less Than</i>
CLEARWATER	0.8	2004	NA
SALMON	0.1	2003	NA
WEISER	-1.3	2004	NA
PAYETTE	-0.8	2003	NA
BOISE	-0.4	2008	-2.2
BIG WOOD	-1.5	2008	-0.7
LITTLE WOOD	-0.2	2003	-2.1
BIG LOST	-0.4	2003	-0.1
LITTLE LOST	-1.3	2006	0.6
HENRYS FORK	-0.1	2006	-3.3
SNAKE (HEISE)	0.4	1980	-1.5
OWYHEE	-3.0	2002	-3.0
OAKLEY	-1.3	1993	-1.1
SALMON FALLS	-1.5	1989	-1.5
BRUNEAU	-0.9	2008	NA
BEAR RIVER	-2.6	1993	-3.5

SWSI SCALE, PERCENT CHANCE OF EXCEEDANCE, AND INTERPRETATION

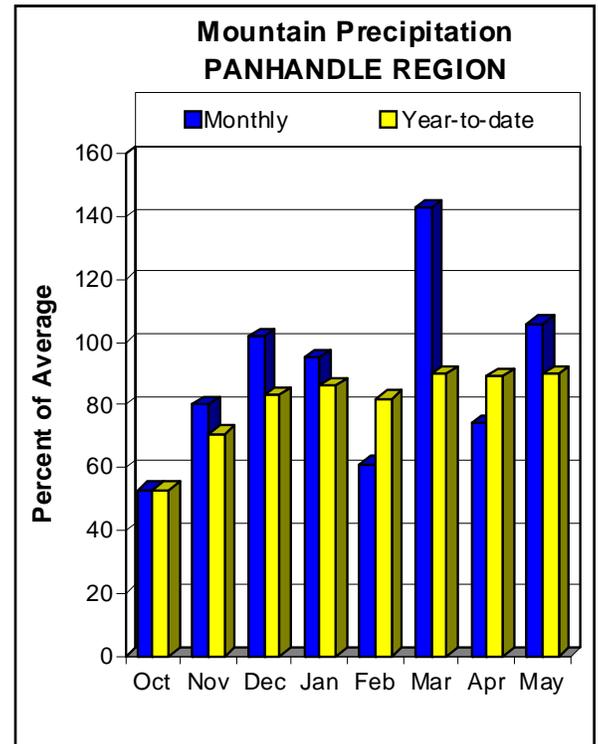

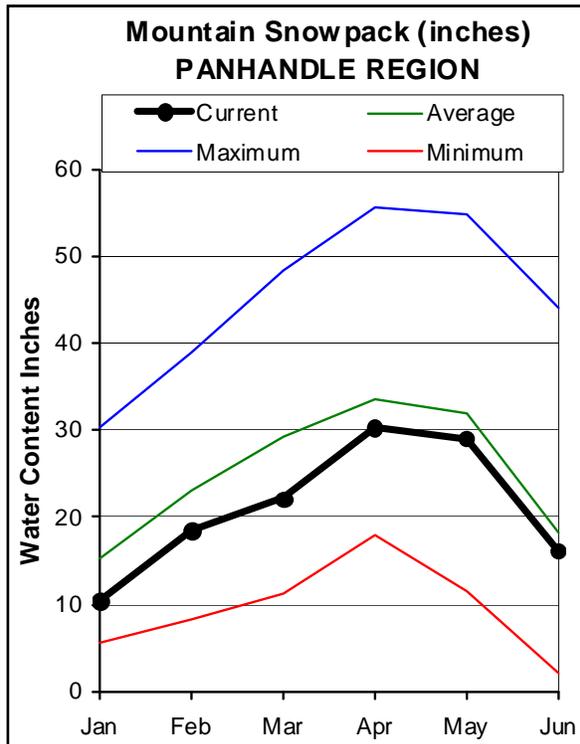

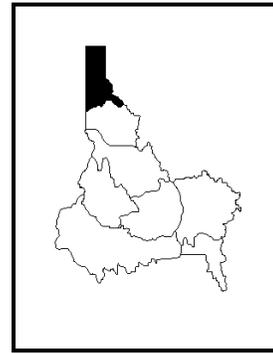

NA = Not Applicable

Note: The Percent Chance of Exceedance is an indicator of how often a range of SWSI values might be expected to occur. Each SWSI unit represents about 12% of the historical occurrences. As an example of interpreting the above scale, the SWSI can be expected to be greater than -3.0, 87% of the time and less than -3.0, 13% of the time. Half the time, the SWSI will be below and half the time above a value of zero. The interval between -1.5 and +1.5 described as "Near Normal Water Supply," represents three SWSI units and would be expected to occur about one-third (36%) of the time.

PANHANDLE REGION

JUNE 1, 2009

WATER SUPPLY OUTLOOK

The month of May marks only the second month besides March with above average precipitation since January. The water year-to-date precipitation is 90% of average as of June 1. The winter's snowpack has melted below 5000 feet according to the SNOTEL sites. Above that elevation band on June 1, the snow ranged from 41% of average in the Coeur d'Alene River basin, 69% in the Moyie, 78% in the Spokane, 87% in the Kootenai above Bonners Ferry, near 95% in the St. Joe and Pend Oreille River up to 104% of average in the Priest River drainage. The streamflow forecasts for the Kootenai, Priest, North Fork Coeur d'Alene and the Spokane are near 90% of average. The Moyie River, Boundary and Smith Creeks are forecast at 78% 73%, 80% of normal, respectively. The best streamflow volume forecast can be found where the mountains held onto their snow in the Priest River, which is forecast at 94% of average for June through September.

* 90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual flow will exceed the volumes in the table.

- (1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.
- (2) - The value is natural flow - actual flow may be affected by upstream water management.

CLEARWATER RIVER BASIN

JUNE 1, 2009

WATER SUPPLY OUTLOOK

This snow year, the Clearwater started off slow in January and then made up for lost time since March. May brought 106% of average precipitation to the Clearwater SNOTEL sites, which is part of the near average precipitation for the entire water year. The snow waited until May to start melting and lost over an inch of snow water per day once the sun started shining. The snow that is left is at 92% of average overall for the Clearwater basin. The best snowpack is in the Selway basin at 106% of average. The North Fork Clearwater has 89% of average snow and the Lochsa lost the most and is 73% of average. These rivers have been flowing high during the last few weeks of May. The Clearwater, Lochsa and Selway have all had greater than 110% of average volumes of water coming down the channels for the past month. The Selway River near Lowell had the highest volume with respect to average at 128%! The highest daily instantaneous peak so far occurred on May 31 at 31,900cfs around 2am. There may be another peak left depending on how the remaining snow melts and if rain or hot temperatures occur. As far as seasonal volume streamflow forecasts go, the outlook is for 104% of average flows through September for the Selway, 90% for the Lochsa and 95-100% for the Clearwater. These flows and Dworshak's 90% full status should provide excellent river recreation opportunities and lake days through the summer whether you like whitewater, power boating or more relaxed floating and fishing.

SALMON RIVER BASIN

JUNE 1, 2009

WATER SUPPLY OUTLOOK

Once again, the Salmon basin had an average month of precipitation during the month of May and the water year-to-date precipitation is 95% of average for the first of June. Current snowpack is 67% of average overall for the Salmon basin. The snowpack reached its average peak snow water content earlier this year and some sites well surpassed the average. The snowpack has been melting fast over the last few weeks; up to two inches of water per day at some sites. There is no snow left at the snow sites in the little Salmon drainage; the snow is 43% of average in the South Fork; near 65% in the Middle Fork and Salmon above Salmon drainages and up to 90% of average snow is left in the Lemhi basin. The fast melting snow caused rivers to rise. May streamflow volumes for the Middle Fork Salmon at MF Lodge was 141% of average; and near 120% of average for the main River of no Return at White Bird. Streamflow forecasts call for 80-91% of average volumes to flow by these Salmon stream gages through September, which will lead to a very good river recreation season barring too hot and dry conditions.

WEISER, PAYETTE, BOISE RIVER BASINS JUNE 1, 2009

WATER SUPPLY OUTLOOK

The month of May's 136% of average precipitation improved the summer streamflow forecasts. These west-central Idaho Mountains struggled this winter for accumulating snow, and as of June 1 this region only had half of normal snow. The Weiser basin SNOTEL sites have melted and the Boise and Payette are both near 50% of normal; the South Fork Payette highlands has the most snow in the region at 65% of normal. The good spring precipitation has improved the water supply picture and the forecasts for June through September streamflow are now in the 60-77% range. The highest streamflow volume forecast is for the South Fork Payette River at Lowman at 77% of normal. Except in the Weiser basin, forecast at 65% of average, the regional water supply should be adequate since the Boise and Payette reservoir systems are near full and above average at the end of May.

(2) - The value is natural flow - actual flow may be affected by upstream water management.

WOOD and LOST RIVER BASINS

JUNE 1, 2009

WATER SUPPLY OUTLOOK

The SNOTEL sites near 9,000 feet are the only sites with snow left in the Wood and Lost basins, which equates to 35% of average snow water content overall as of June 1. The precipitation in May was only 83% of average leaving the water year-to-date precipitation at 94% of average. The rapidly melting snow and the low spring precipitation conditions have caused the streamflow forecasts to drop some from last month. The Little Wood and Big Wood River streamflow June-September forecasts are for 49-62% of normal; followed by the Big Lost and Little Lost rivers forecast at about 68% of average during the same period. As of June 1, the Little Wood Reservoir is almost full, while Mackay Reservoir is 86% of capacity, and both reservoirs are almost 110% of average. Magic Reservoir has had the toughest time with these low snow years and is only 57% full; 70% of average. Water supplies will be tight for water users that are downstream of Magic Reservoir especially. However, if cool and wet conditions continue, then the impacts will be less severe.

UPPER SNAKE BASINS

JUNE 1, 2009

WATER SUPPLY OUTLOOK

The past three out of four years, the snowpack has been above average in the upper Snake Basin in May. Each year has behaved slightly different during snowmelt and runoff. Last year, the temperatures remained cold and the snow was 149% of average on June 1. On June 1, 2006, the snow was 72% of normal and began melting quickly during mid-May with warm temperatures. This year the snow is 69% of normal on the same date and some of the SNOTEL sites above 8500 feet are hanging on to above average snow amounts for this time of year. The water year-to-date precipitation is average for this time of year even though the precipitation during the month of May was only 85% of average. The rivers in the upper Snake basin had above average streamflow volumes during the month of May. The streamflows have helped most of the reservoirs in the upper Snake to store near average or better amounts. Henrys Lake, Grassy Lake, Island Park, Ririe and American Falls are full or near full. Palisades is 67% full and Jackson is 88% of capacity. Good snow, good precipitation and good reservoir storage means good streamflow forecasts through September. However, the above average streamflow that has already occurred during May will keep the summer streamflows from reaching above average volumes through September. The best forecasts are where the pockets of good June 1 snow still exist: Pacific Creek near Moran is forecast at 108%; the Snake at Flagg Ranch, the Greys and Salt Rivers are forecast at near average volumes through September. Streams that are forecast in the 85-95% of average range are: the Henrys Fork, Falls River, Teton River, Snake near Moran, above the Reservoir near Alpine, near Heise and also near Irwin. The lowest seasonal volume forecasts are for further downstream at the Portneuf near Topaz at 75% of average and the Snake River near Neeley at 66% of normal. Water supplies should be adequate for most water users this summer. Wet and cool conditions will improve the situation even more.

SOUTHSIDE SNAKE RIVER BASINS JUNE 1, 2009

WATER SUPPLY OUTLOOK

The southside Snake reservoirs are only about half full and about 75% of average, this includes: Salmon Falls, Oakley, Wildhorse and Lake Owyhee. The snow has melted at the SNOTEL sites in the Owyhee Mountains, Bruneau and Salmon Falls drainages, only the highest elevations has snow. The good news is that the mountains received a near normal snowpack this year overall; even if it melted out a little early. The precipitation for May was only 74% of average, but other good months of precipitation resulted in the water year-to-date precipitation at 104% of average as of June 1. Besides the low reservoir storage, cumulative dry years since 2000 have resulted in low streamflow volume forecasts in the past years. Current streamflow forecasts range from near 50% of normal for the Owyhee River and Salmon Falls Creek, to 60-65% for the Bruneau River and Oakley Reservoir inflow.

BEAR RIVER BASIN

JUNE 1, 2009

WATER SUPPLY OUTLOOK

Precipitation for the Bear River basin remains at average values for the water year-to-date. Although precipitation during the past few months was above average, May precipitation was only 73% of average. The snowpack was only half of normal on June 1 because of the melt during the last few weeks of May but the mountains did manage to receive a near normal snowpack earlier this year. The streamflow forecasts call for near 90% of average volumes of water to flow down the channels for most of the rivers in the Bear basin through September. The best flow with respect to average is forecast to occur at the Bear River near the Utah-Wyoming border and above the Reservoir at 100% average through September. The lowest flow will occur below Stewart Dam at 63% of average. The Bear River water users will be able to meet their needs based on the Surface Water Supply Index (SWSI), which combines current Bear Lake storage and the 50% Exceedance Streamflow Volume Forecast. If spring continues to bring cool temperatures and precipitation, then water users can expect more water, and less if the temperatures are hot and the weather is dry.

Streamflow Adjustment List for All Forecasts Published in Idaho Water Supply Outlook Report: streamflow forecasts are projections of runoff volumes that would occur without influences from upstream reservoirs or diversions. These values are referred to as natural, unregulated or adjusted flows. To make these adjustments, changes in reservoir storage, diversions, and inter-basin transfers are added or subtracted from the observed (actual) streamflow volumes. The following list documents the adjustments made for each forecast point. **(Revised Nov. 2007).**

Reservoir Capacity Definitions (Units in 1,000 Acre-Feet, KAF)

Different agencies use various definitions when reporting reservoir capacity and contents. Reservoir storage terms include dead, inactive, active, and surcharge storage. This table lists volumes for each reservoir, and defines the storage volumes NRCS uses when reporting capacity and current storage. In most cases, NRCS reports usable storage, which includes active and inactive storage. **(Revised Dec. 2005)**

Basin/ Reservoir	Dead Storage	Inactive Storage	Active Storage	Surcharge Storage	NRCS Capacity	NRCS Capacity Includes
<u>Panhandle Region</u>						
Hungry Horse	39.73	---	3451.00	---	3451.0	Active
Flathead Lake	Unknown	---	1791.00	---	1791.0	Active

Interpreting Water Supply Forecasts

Introduction

Each month, five forecasts are issued for each forecast point and each forecast period. Unless otherwise specified, all streamflow forecasts are for streamflow volumes that would occur naturally without any upstream influences. Water users need to know what the different forecasts represent if they are to use the information correctly when making operational decisions. The following is an explanation of each of the forecasts.

90 Percent Chance of Exceedance Forecast. There is a 90 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 10 percent chance that the actual streamflow volume will be less than this forecast value.

70 Percent Chance of Exceedance Forecast. There is a 70 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 30 percent chance that the actual streamflow volume will be less than this forecast value.

50 Percent Chance of Exceedance Forecast. There is a 50 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 50 percent chance that the actual streamflow volume will be less than this forecast value. Generally, this forecast is the middle of the range of possible streamflow volumes that can be produced given current conditions.

30 Percent Chance of Exceedance Forecast. There is a 30 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 70 percent chance that the actual streamflow volume will be less than this forecast value.

10 Percent Chance of Exceedance Forecast. There is a 10 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 90 percent chance that the actual streamflow volume will be less than this forecast value.

*Note: There is still a 20 percent chance that actual streamflow volumes will fall either below the 90 percent exceedance forecast or above the 10 percent exceedance forecast.

These forecasts represent the uncertainty inherent in making streamflow predictions. This uncertainty may include sources such as: unknown future weather conditions, uncertainties associated with the various prediction methodologies, and the spatial coverage of the data network in a given basin.

30-Year Average. The 30-year average streamflow for each forecast period is provided for comparison. The average is based on data from 1971-2000. The % AVG. column compares the 50% chance of exceedance forecast to the 30-year average streamflow; values above 100% denote when the 50% chance of exceedance forecast would be greater than the 30-year average streamflow.

AF - Acre-feet, forecasted volume of water are typically in thousands of acre-feet.

These forecasts are given to users to help make risk-based decisions. Users can select the forecast corresponding to the level of risk they are willing to accept in order to minimize the negative impacts of having more or less water than planned for.

To Decrease the Chance of Having Less Water than Planned for

A user might determine that making decisions based on a 50 percent chance of exceedance forecast is too much risk to take (there is still a 50% chance that the user will receive less than this amount). To reduce the risk of having less water than planned for, users can base their operational decisions on one of the forecasts with a greater chance of being exceeded such as the 90 or 70 percent exceedance forecasts.

To Decrease the Chance of Having More Water than Planned for

A user might determine that making decisions based on a 50 percent chance of exceedance forecast is too much risk to take (there is still a 50% chance that the user will receive more than this amount). To reduce the risk of having more water than planned for, users can base their operational decisions on one of the forecasts with a lesser chance of being exceeded such as the 30 or 10 percent exceedance forecasts.

Using the forecasts - an Example

Using the 50 Percent Exceedance Forecast. Using the example forecasts shown below, there is a 50% chance that actual streamflow volume at the Boise River near Twin Springs will be less than 685 KAF between April 1 and July 31. There is also a 50% chance that actual streamflow volume will be greater than 685 KAF.

Using the 90 and 70 Percent Exceedance Forecasts. If an unexpected shortage of water could cause problems (such as irrigated agriculture), users might want to plan on receiving 610 KAF (from the 70 percent exceedance forecast). There is a 30% chance of receiving *less* than 610 KAF.

Alternatively, if users determine the risk of using the 70 percent exceedance forecast is too great, then they might plan on receiving 443 KAF (from the **90** percent exceedance forecast). There is 10% chance of receiving less than 443 KAF.

Using the 30 or 10 Percent Exceedance Forecasts. If an unexpected excess of water could cause problems (such as operating a flood control reservoir), users might plan on receiving 760 KAF (from the 30 percent exceedance forecast). There is a 30% chance of receiving *more* than 760 KAF.

Alternatively, if users determine the risk of using the 30 percent exceedance forecast is too great, then they might plan on receiving 927 KAF (from the 10 percent exceedance forecast). There is a 10% chance of receiving more than 927 KAF.

Users could also choose a volume in between any of these values to reflect their desired risk level.

Weiser, Payette, Boise River Basins Streamflow Forecasts – January 2006								
Forecast Point	Forecast Period	Chance of Exceeding *						
		90% (1000AF)	70% (1000AF)	50% (1000 AF)	(% AVG.)	30% (1000AF)	10% (1000AF)	30-Yr Avg. (1000AF)
SF PAYETTE RIVER at Lowman	APR-JUL	329	414	471	109	528	613	432
	APR-SEP	369	459	521	107	583	673	488
BOISE RIVER near Twin Springs (1)	APR-JUL	443	610	685	109	760	927	631
	APR-SEP	495	670	750	109	830	1005	690

*90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual flow will exceed the volumes in the table
