# Idaho Water Supply Outlook Report January 1, 2012

The minus signs on this map represent the record or near record low Christmas snowpacks at many SNOTEL sites across Idaho and the West. Such dry conditions were surprising since cold ocean temperatures, that signal a La Nina, have been measured in the Pacific Ocean ever since last winter. La Nina conditions are often touted as producing cold and stormy winters in the Pacific Northwest. Last winter was a textbook example. While this year's La Nina is not as strong as last year, climate models are still predicting above average conditions in the coming months. The weather pattern shifted in late December bringing long anticipated snow to Idaho. Hopefully the snow will continue as a significant amount of catch-up is needed to get Idaho's snowpack back to above average amounts.

## *How forecasts are made*

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when the snow melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation, antecedent streamflow, and indices of the El Niño / Southern Oscillation are used in computerized statistical and simulation models to produce runoff forecasts. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertainty is in the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they may want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they may want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

# **IDAHO WATER SUPPLY OUTLOOK REPORT**

**JANUARY 1, 2012**

## **SUMMARY**

Idaho is waiting for the one-two punch to improve the snowpack and water supply outlook. The stage seemed set with a rerun of La Nina. The first 45 days of the new water year, which began on October 1, brought ample fall rains followed by early November snow. After mid-November, the only punch felt was cold temperatures with the exception of northern Idaho. Then, in late December moisture laden storms finally arrived for the next punch, but rain fell at elevations over 7,000 feet in central Idaho. Snowpacks are below average across the state with the Owyhee basin pushing near record low levels. The good news is that the soil moisture deficit has been nearly erased from the October rains and that reservoirs are storing near average to above average water levels across the state. Streamflow forecasts mirror the snowpacks and call for 30-75% of average April through July volumes for most of the state and near 85% of average in the Panhandle region. With more than half the winter still to come, conditions can improve by delivering the one-two punch: cold temperatures combined with Pacific moisture. Long-term climate forecasts still cite La Nina conditions in the Pacific Ocean, and predict above average precipitation for the coming months.

## **SNOWPACK**

An extended dry spell since Thanksgiving left 22 SNOTEL sites with record or near record low snow amounts by Christmas Day. The last week of December brought a long, anticipated series of storms into the state. However, much of the moisture began falling as rain as high up as 7,000 feet and in places such as Jackson, Wyoming. The powerful storm finished with high winds followed by a sharp drop in temperatures and snow. The storm even brought some thunder and lightning to the Treasure Valley on December 30. As a result of the recent storm cycle, the number of record low snowpacks at SNOTEL sites decreased. On January 1, the record low snowpacks are located in the Owyhee and Bruneau basins at only near 26-35% of average. Elsewhere across southern Idaho the snowpacks range from 35-60% of average. Central Idaho snowpacks are 55-65% of average while the highest snowpacks remain in northern Idaho at 65-90% of average.

## **PRECIPITATION**

The water year started in October with the state receiving 1 to 2.5 times the normal monthly precipitation amounts. This helped to erase the annual summer soil moisture deficit across most of the state. November brought an early snow storm before Thanksgiving, but then gave way to a stagnant weather pattern of blue skies during the day and clear skies at night for nearly 30 days. November precipitation ranged from half of average in southern Idaho to just over average in northern Idaho. December's precipitation would have been disappointing if not for the stormy last week of the month which raised monthly precipitation amounts to 40-60% across the state, except in southern Idaho which received less than one-third of average amounts. On the bright side, water year-to-date precipitation amounts are near average in the Little Wood, Big Lost and Little Lost basins and are 60-90% elsewhere in the state.

## **RESERVOIRS**

Excellent carryover storage from last year will provide a relief for water users if snowpacks remain below average. Concern of too much water in storage faded with the extended period of blue skies. Current storage amounts range from 50-85% of capacity and are near average to well above average state-wide. Fortunately, minimal spring runoff is needed to provide adequate irrigation supplies in the Salmon Falls, Oakley and Bear River basins because of the carryover storage.

Note: NRCS reports reservoir information in terms of usable volumes, which includes both active, inactive and in some cases, dead storage. Other operators may report reservoir contents in different terms. For additional information, see the reservoir definitions in this report.

## **STREAMFLOW**

Throughout Idaho, streamflow in most rivers was above average from last spring through this November, when the thermometer began to drop and the skies cleared. The sustained high streamflows highlight the impressive impact that last year's snowpack and precipitation had on baseflows. The late December precipitation thawed some streams and caused some short-lived stream peaks that have already subsided. Summer streamflow forecasts mirror the current snowpack conditions with the lowest flows forecast in the Owyhee and Bruneau basins at 30-50% of average and highest in northern Idaho at 75-89% of average. To honor a request, the NRCS will start forecasting the natural flow this year for Camas Creek at Camas near Mud Lake to assist water managers at Camas National Wildlife Refuge.

Note: Forecasts published in this report are NRCS forecasts. NRCS uses timely SNOTEL data to provide streamflow forecasts. Jointly coordinated published forecasts by the USDA NRCS and the NOAA NWS are available from the joint west-wide Water Supply Outlook for the Western US at <http://www.wcc.nrcs.usda.gov/wsf/westwide.html>. Water users may wish to use a lesser exceedance forecast to reduce the risk of coming up water short or greater volume to mitigate high flow potential.

## **RECREATION**

If ice skating on glassy, snow-free lakes is your winter passion December 2011 may go down as your all-time favorite. Otherwise winter recreation has been pretty limited through Christmas for most of Idaho. Two-thirds of our SNOTEL sites had less than two feet of snow on the ground through December 27th. Only high elevation sites in Northern Idaho and western Wyoming saw more than 3 feet of snow. One note of caution, avalanche centers across the region are warning of a weak, faceted snowpack underlying the new snow. Check local advisories at [www.avalanche.org](http://www.avalanche.org) and use caution before proceeding in the mountains.

## **Implementation of 1981–2010 Period Climate Normals Delayed until October 1, 2012**

The NRCS Snow Survey and Water Supply Forecasting Program follows the World Meteorological Organization (WMO) conventional standard for climate normals when comparing current data to historic trends. The WMO has established a 30-year reference period "as it is long enough to filter out any interannual variation or anomalies, but also short enough to be able to show longer climatic trends".

([http://www.wmo.int/pages/themes/climate/climate\\_data\\_and\\_products.php](http://www.wmo.int/pages/themes/climate/climate_data_and_products.php)). Climate normals are updated every ten years, and NRCS as well as other agencies like the National Weather Service are currently in the process of changing from the 1971–2000 period to the new 1981–2010 period. The most recent 30 year period is said to represent the current climatological conditions; that is why a 30 period is used instead of a longer period.

The full implementation of the "new" normals for all NRCS applications is planned for the beginning of the 2013 water year on October 1, 2012. In the meantime, all reports and products including streamflow forecasts for the current water year will continue using the 1971–2000 normals. Normal values of both medians and averages will be produced for all parameters and available to the public. Please contact the Idaho Snow Survey Office or watch our home Internet page for more information.

### **1981-2010 Climate Normals will use a Combination of Means and Median**

The values presented as the "NRCS official" 1981-2010 30-year normals, whether daily, monthly, annual or seasonal (April – July period for example), will be the arithmetic mean (i.e., average) of the 30 individual yearly data for the following parameters: streamflow volume acre-feet, reservoir storage acre-feet, SNOTEL and NWS precipitation, and snow depth (manual snow courses only). SNOTEL sites do not have enough years of automated snow depth to produce reliable normals. However, the normal values presented for the snow water equivalent (SWE) parameter will be the statistical median of the 30 individual yearly data for both manual snow courses and daily SNOTEL data. This is a departure from previous years when all parameters used the average (mean) values.

Climate data specialists are nearly unanimous in the opinion that the SWE median better represents a normal condition for a parameter that accumulates and dissipates in a seasonal pattern with great variation. As an example, think of a site that hardly ever has snow water on the ground on June 1. The perception is that the "normal" condition is more or less zero snow for June 1. Now, if you add an extreme year, like June 2011, the arithmetic mean value might end up being a couple inches. In this case the mean does not represent the normal or most expected condition; however, the median which would probably be zero, makes a better normal. In 2001 when the averages were updated, the average Julian start and melt out dates were calculated and used to define the start and end points for the 1971-2000 SWE averages in Idaho. This new method of using medians now provides consistency West-wide.

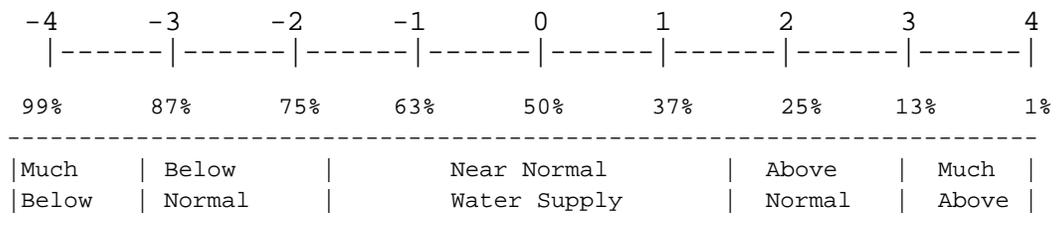

**IDAHO SURFACE WATER SUPPLY INDEX (SWSI)      January 1, 2012**

The Surface Water Supply Index (SWSI) is a predictive indicator of surface water availability within a watershed for the spring and summer water use season. The index is calculated by combining pre-runoff reservoir storage (carryover) with forecasts of spring and summer streamflow. SWSI values are scaled from +4.0 (abundant supply) to -4.0 (extremely dry), with a value of zero indicating a median water supply as compared to historical occurrences. The SWSI analysis period is from 1971 to present.

SWSI values provide a more comprehensive outlook of water availability by combining streamflow forecasts and reservoir storage where appropriate. The SWSI index allows comparison of water availability between basins for drought or flood severity analysis. Threshold SWSI values have been determined for some basins to indicate the potential for agricultural irrigation water shortages.

<i><b>BASIN or REGION</b></i>	<i><b>SWSI Value</b></i>	<i><b>Most Recent Year With Similar SWSI Value</b></i>	<i><b>Agricultural Water Supply Shortage May Occur When SWSI is Less Than</b></i>
Northern Panhandle	-0.4	1995	NA
Spokane	-0.7	2010	NA
Clearwater	-1.7	2010	NA
Salmon	-1.4	2000	NA
Weiser	-1.7	2004	NA
Payette	-1.4	2004	NA
Boise	0.7	2007	-1.3 to -1.6
Big Wood	0.6	2011	0.5 to 0.7
Little Wood	0.7	2005	-1.3 to -1.6
Big Lost	-0.4	2010	0.3 to 0.5
Little Lost	-1.2	2008	1.0 to 1.3
Teton	-0.9	2005	NA
Henry's Fork	-0.8	2010	-3.4 to -3.6
Snake (Heise)	0.9	2008	-1.3 to -1.6
Oakley	1.4	2000	0.3 to 0.5
Salmon Falls	0.1	2010	-0.4 to -0.8
Bruneau	-2.4	2003	NA
Owyhee	0.4	2005	-3.0 to -3.5
Bear River	2.0	2011	-2.3 to -2.6

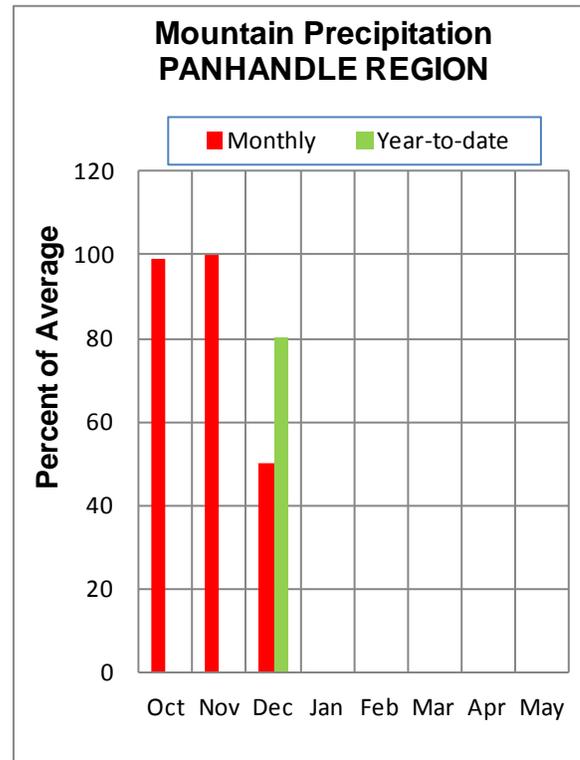

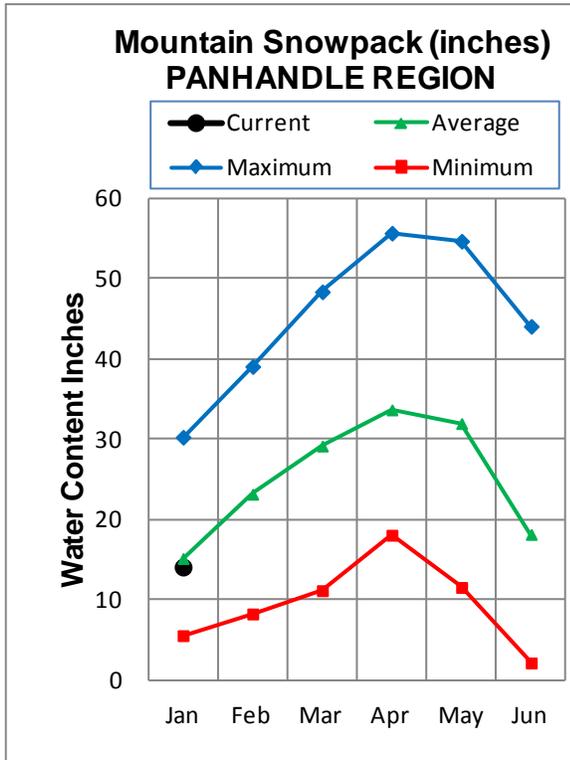

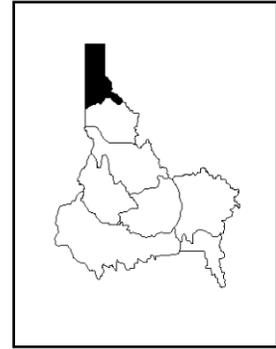

**SWSI SCALE, PERCENT CHANCE OF EXCEEDANCE, AND INTERPRETATION**

NA = Not Applicable, Note: The Percent Chance of Exceedance is an indicator of how often a range of SWSI values might be expected to occur. Each SWSI unit represents about 12% of the historical occurrences. As an example of interpreting the above scale, the SWSI can be expected to be greater than -3.0, 87% of the time and less than -3.0, 13% of the time. Half the time, the SWSI will be below and half the time above a value of zero. The interval between -1.5 and +1.5 described as "Near Normal Water Supply," represents three SWSI units and would be expected to occur about one-third (36%) of the time.

# PANHANDLE REGION

## JANUARY 1, 2012

### WATER SUPPLY OUTLOOK

The Idaho panhandle region's mountains have an 84% of average snowpack on January 1, while the rest of the state has snowpack levels lower than this. The best snow can be found in the Moyie and Priest River drainages at near 95% of average and the lowest in the St. Joe at 66% of average. Based on the current snowpack and the La Nina conditions expected, these mountains should be in good shape through the winter making water users happy in the spring. Reservoirs are about 40% of capacity and the rivers are expected to run about 80-90% of average from April through July. While any range of weather conditions are possible throughout the rest of the winter, the Panhandle region is leaning towards having an adequate summer water supply season even though it has seemed dry so far.

\* 90%, 70%, 50%, 30%, and 10% chances of exceeding are the probabilities that the actual volume will exceed the volumes in the table.

The average is computed for the 1971-2000 base period.

- (1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.
- (2) - The value is natural volume - actual volume may be affected by upstream water management.

# CLEARWATER RIVER BASIN

JANUARY 1, 2012

## WATER SUPPLY OUTLOOK

La Nina hasn't produced the desired snowpack in the Clearwater basin yet this winter. As of January 1, the snowpack is 77% of normal and lagging behind the neighboring basins to the north. A powerful storm moved through before New Year's Day but more rain fell than snow below 6000 feet of elevation. Conversely, the higher elevation sites received almost 2 new feet of snow. The rain and warmer temperatures broke up some river ice and caused some mid-winter streamflow peaks; not near as intense as last January's runoff event. For instance, the Clearwater at Orofino was frozen on December 29th, and then jumped to a daily mean flow of 6,630 cfs on New Year's Eve. Last January, the River was not frozen but jumped from around 2,500 cfs to 28,900 cfs over a few days! Hopefully, La Nina will carry its weight and bring the expected snow this winter. If it lags, Dworshak Reservoir has 91% of average storage and is 65% of capacity. The streamflow forecasts call for 75% of average volumes for Dworshak Reservoir inflow and about 85% for the Clearwater, Lochsa and Selway Rivers for the April through July period. These forecasts will increase over the next few months as the finger crossing brings the snow.

# SALMON RIVER BASIN

## JANUARY 1, 2012

### WATER SUPPLY OUTLOOK

Every year is unique, but the hope is that the slow start to winter this year will be offset by the usual stormy weather that occurs during a La Nina year. Recall from a recent La Nina year such as 2009, where winter was delayed early in the season but the snowpack caught up to average later in the season before snowmelt began. Last year, the snowpack started off on a better note, lingered late into spring and ended up being the 2nd highest snowpack on SNOTEL records for June 1. The long dry spell this past December results in a 72% of average January 1st snowpack. The water year-to-date precipitation is slightly better on January 1 at 81% of average due to rainfall before the snow began accumulating. Any combination of big storms over the next few months or late lingering snowpacks similar to these historical La Nina years will leave behind a favorable water supply picture this spring. It is too early in the season to say for sure and there have been too many recent weather anomalies to be confident in the summer water supply outlook on this January 1. However, based on the current conditions, the streamflow forecasts call for about 65-75% of average volumes for the Salmon River and its tributaries; enough water for fun on the rivers this spring.

# WEISER, PAYETTE, BOISE RIVER BASINS

## JANUARY 1, 2012

### WATER SUPPLY OUTLOOK

The water year got off to a good start in October, but dry conditions in November and December have the West Central Mountains playing catch-up. Water year-to-date precipitation is 80% of normal. Monthly Precipitation was 153% of normal in October, 71% of normal in November and only 59% of normal for December. Through December 27th, 17 of 22 SNOTEL sites in the region had seen 0.2 inches or less precipitation for the month. Usual December precipitation at these sites is about 6 inches. These bone dry skies from Thanksgiving to Christmas produced record low Christmastime snow amounts when compared to 30 years of daily SNOTEL measurement at Mores Creek Summit and Deadwood Summit. A number of other sites ranked second lowest with only 1989 having less snow. Fortunately the large storm starting on December 28 increased snowpack amounts to 69% of average by January 1. Prior to that storm, the snowpack was only about 45% of normal. Although snowpacks are low, good reservoir storage provides some security for water users at this point. Reservoir storage amounts are above average in both the Boise and Payette basins. Summer streamflow forecasts call for 63-80% of average for the April-July period. Hopefully the recent storm cycle is an indication of what to expect in the coming months while there is still time for snowpacks to reach normal levels by April.

# WOOD and LOST RIVER BASINS

JANUARY 1, 2012

## WATER SUPPLY OUTLOOK

The Wood and Lost basins got off to the best start in the state this water year, but since October all bragging rights have been revoked. For a while it looked like La Nina was picking up right where it left off last spring. October brought 241% of the normal monthly precipitation to central Idaho, breaking a number of SNOTEL precipitation records for the month. After 72% of normal November precipitation and only 50% in December, the water year-to-date precipitation on January 1 is 96%. Snowpacks across these four basins currently range from 53-70% of normal with the highest amounts in the Big Wood basin. The fall rains helped to remove soil moisture deficits from last summer. Magic Reservoir is 142% of average, best since 1999; Little Wood is 167% of average while Mackay is 139% of average, all are about two-thirds full. Streamflow forecasts call for 50-85% of average summer streamflow volumes. Although streamflow forecasts are low, reservoir storage combined with a few good storms should provide adequate irrigation supplies.

# UPPER SNAKE BASIN

## JANUARY 1, 2012

### WATER SUPPLY OUTLOOK

Like siblings with the same genes but polar opposite personalities, this year's La Nina is shaping up quite different than last winter's La Nina. Last winter came close to equaling maximum snow records in the Upper Snake; by comparison this winter has started with one of the lowest. Fall precipitation was above average in October (146% for the month) and near average in November (96%), however the clouds dried up for most of December which saw far below average amounts (52%). Water year-to-date precipitation since October currently stands at 89% of average. Snowpacks were on track until Thanksgiving when a ridge of high pressure blocked additional precipitation. Snowpacks held steady with a month of cold weather and very little accumulation until Christmas. Blind Bull SNOTEL, in the Greys River basin, and Phillips Bench, on Teton Pass, each recorded the least amount of snow ever measured on December 27 based on 31 years of daily data. Fortunately, the high pressure broke down and the winter's first big storm delivered abundant moisture totaling up to 4 inches of water at higher elevation SNOTEL sites. Currently, snowpacks across the watershed range from 60-64% of average in the Greys, Salt and Hoback basins to 90% above Jackson Lake. Although snow amounts are low for the most part in the basin, water users are pleased to see water in the bank accounts; combined storage for the 8 major reservoirs in the Upper Snake is 113% of average, 73% of capacity. Streams are forecast at 73-99% of average for the April-July period and should be enough for adequate irrigation supplies. Hopefully the La Nina we knew last year returns for the rest of this winter.

# SOUTHSIDE SNAKE RIVER BASINS

JANUARY 1, 2012

## WATER SUPPLY OUTLOOK

With the exception of above normal precipitation in October, the Southside Snake basins have been very dry this water year and currently host the lowest snowpack in Idaho. The new water year started on the right foot, receiving 168% of average precipitation in October. November started to dry out with only 57% of average precipitation falling and got worse in December with only 25% falling across the region. The Owyhee was the driest basin in December with only 17% of normal precipitation for the month. Most SNOTEL sites had less than an inch of precipitation for the month. Snowpacks range from a low of 26% of average in the Owyhee basin to 35% in the Bruneau, 41% in the Salmon Falls basin and 51% in the Goose Creek basin. Streamflow forecasts mirror the snow and call for below average amounts ranging from 29-65% across the region. Despite below average conditions, reservoir storage across the region is excellent and provides water users a buffer for this summer. Owyhee Reservoir is 124% of average, 69% full and currently has over 450,000 acre-feet, which is the threshold needed to meet irrigation demand. Salmon Falls and Oakley reservoirs are also storing above average amounts and need only minimal runoff this spring to meet irrigation demands.

# BEAR RIVER BASIN

## JANUARY 1, 2012

### WATER SUPPLY OUTLOOK

Water year 2011 will be remembered as a stellar water year in the Bear River basin but this year may be remembered for the opposite. The April-July 2011 streamflow was 260% of average for the Bear River at Stewart Dam; this year Stewart Dam is forecast to be 65% of average for the same period. A year ago the lake was storing only 516,000 acre-feet. Today, the lake is storing 1,077,900 acre-feet, the highest January 1 amount since 1999. Minimal spring runoff is needed for reservoir storage water users. Monthly precipitation for October was 128% of average; November brought 86% and December saw only a quarter of its normal amount. As a result, snowpacks range from 40-60% of average across this region. Since 1991, 7 out of 16 years that had a below normal snowpack on January 1, increased to an April 1 snowpack of 80% of average or better. Hopefully, we can add another year to that record.

\* 90%, 70%, 50%, 30%, and 10% chances of exceeding are the probabilities that the actual volume will exceed the volumes in the table.

The average is computed for the 1971-2000 base period.

- (1) - The values listed under the 10% and 90% Chance of Exceeding are actually 5% and 95% exceedance levels.
- (2) - The value is natural volume - actual volume may be affected by upstream water management.

**Streamflow Adjustment List for All Forecasts Published in Idaho Water Supply Outlook Report:** Streamflow forecasts are projections of runoff volumes that would occur without influences from upstream reservoirs or diversions. These values are referred to as natural, unregulated or adjusted flows. To make these adjustments, changes in reservoir storage, diversions, and inter-basin transfers are added or subtracted from the observed (actual) streamflow volumes. The following list documents the adjustments made for each forecast point. **(Revised Dec 2011).**

### **Panhandle River Basins**

Kootenai R at Leonia, MT

+ Lake Koocanusa storage change

Moyie R at Eastport – no corrections

Little Bear R at Paradise, UT - no corrections

Logan R nr Logan, UT - no corrections

Blacksmith Fk nr Hyrum, UT - no corrections

### Reservoir Capacity Definitions (Units in 1,000 Acre-Feet, KAF)

Different agencies use various definitions when reporting reservoir capacity and contents. Reservoir storage terms include dead, inactive, active, and surcharge storage. This table lists these volumes for each reservoir, and defines the storage volumes NRCS uses when reporting capacity and current reservoir storage. In most cases, NRCS reports usable storage, which includes active and inactive storage. (Revised Dec 2011)

<u>Basin/ Reservoir</u>	<u>Dead Storage</u>	<u>Inactive Storage</u>	<u>Active Storage</u>	<u>Surcharge Storage</u>	<u>NRCS Capacity</u>	<u>NRCS Capacity Includes</u>
<b><u>Panhandle Region</u></b>						
Hungry Horse	39.73	---	3451.00	---	3451.0	Active
Flathead Lake	Unknown	---	1791.00	---	1791.0	Active

## Interpreting Water Supply Forecasts

### Introduction

Each month, five forecasts are issued for each forecast point and each forecast period. Unless otherwise specified, all streamflow forecasts are for streamflow volumes that would occur naturally without any upstream influences. Water users need to know what the different forecasts represent if they are to use the information correctly when making operational decisions. The following is an explanation of each of the forecasts.

**90 Percent Chance of Exceedance Forecast.** There is a 90 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 10 percent chance that the actual streamflow volume will be less than this forecast value.

**70 Percent Chance of Exceedance Forecast.** There is a 70 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 30 percent chance that the actual streamflow volume will be less than this forecast value.

**50 Percent Chance of Exceedance Forecast.** There is a 50 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 50 percent chance that the actual streamflow volume will be less than this forecast value. Generally, this forecast is the middle of the range of possible streamflow volumes that can be produced given current conditions.

**30 Percent Chance of Exceedance Forecast.** There is a 30 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 70 percent chance that the actual streamflow volume will be less than this forecast value.

**10 Percent Chance of Exceedance Forecast.** There is a 10 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 90 percent chance that the actual streamflow volume will be less than this forecast value.

\*Note: There is still a 20 percent chance that actual streamflow volumes will fall either below the 90 percent exceedance forecast or above the 10 percent exceedance forecast.

These forecasts represent the uncertainty inherent in making streamflow predictions. This uncertainty may include sources such as: unknown future weather conditions, uncertainties associated with the various prediction methodologies, and the spatial coverage of the data network in a given basin.

**30-Year Average.** The 30-year average streamflow for each forecast period is provided for comparison. The average is based on data from 1971-2000. The % AVG. column compares the 50% chance of exceedance forecast to the 30-year average streamflow; values above 100% denote when the 50% chance of exceedance forecast would be greater than the 30-year average streamflow.

AF - Acre-feet, forecasted volume of water are typically in thousands of acre-feet.

These forecasts are given to users to help make risk-based decisions. Users can select the forecast corresponding to the level of risk they are willing to accept in order to minimize the negative impacts of having more or less water than planned for.

### To Decrease the Chance of Having Less Water than Planned for

A user might determine that making decisions based on a 50 percent chance of exceedance forecast is too much risk to take (there is still a 50% chance that the user will receive less than this amount). To reduce the risk of having less water than planned for, users can base their operational decisions on one of the forecasts with a greater chance of being exceeded such as the 90 or 70 percent exceedance forecasts.

### To Decrease the Chance of Having More Water than Planned for

A user might determine that making decisions based on a 50 percent chance of exceedance forecast is too much risk to take (there is still a 50% chance that the user will receive more than this amount). To reduce the risk of having more water than planned for, users can base their operational decisions on one of the forecasts with a lesser chance of being exceeded such as the 30 or 10 percent exceedance forecasts.

### Using the forecasts - an Example

**Using the 50 Percent Exceedance Forecast.** Using the example forecasts shown below, there is a 50% chance that actual streamflow volume at the Boise River near Twin Springs will be less than 685 KAF between April 1 and July 31. There is also a 50% chance that actual streamflow volume will be greater than 685 KAF.

**Using the 90 and 70 Percent Exceedance Forecasts.** If an unexpected shortage of water could cause problems (such as irrigated agriculture), users might want to plan on receiving 610 KAF (from the 70 percent exceedance forecast). There is a 30% chance of receiving *less* than 610 KAF.

Alternatively, if users determine the risk of using the 70 percent exceedance forecast is too great, then they might plan on receiving 443 KAF (from the **90** percent exceedance forecast). There is 10% chance of receiving less than 443 KAF.

**Using the 30 or 10 Percent Exceedance Forecasts.** If an unexpected excess of water could cause problems (such as operating a flood control reservoir), users might plan on receiving 760 KAF (from the 30 percent exceedance forecast). There is a 30% chance of receiving *more* than 760 KAF.

Alternatively, if users determine the risk of using the 30 percent exceedance forecast is too great, then they might plan on receiving 927 KAF (from the 10 percent exceedance forecast). There is a 10% chance of receiving more than 927 KAF.

Users could also choose a volume in between any of these values to reflect their desired risk level.

Weiser, Payette, Boise River Basins Streamflow Forecasts – January 2006								
Forecast Point	Forecast Period	Chance of Exceeding *						
		90% (1000AF)	70% (1000AF)	50% (1000 AF)	50% (% AVG.)	30% (1000AF)	10% (1000AF)	30-Yr Avg. (1000AF)
SF PAYETTE RIVER at Lowman	APR-JUL	329	414	471	109	528	613	432
	APR-SEP	369	459	521	107	583	673	488
BOISE RIVER near Twin Springs (1)	APR-JUL	443	610	685	109	760	927	631
	APR-SEP	495	670	750	109	830	1005	690

\*90%, 70%, 30%, and 10% chances of exceeding are the probabilities that the actual flow will exceed the volumes in the table
