## Water Supply Outlook Report

### May 1st, 2023

**A deep persistent snowpack remains in much of western Colorado including at lower elevations. On May 1<sup>st</sup>, the San Juan Mountains, shown in the above photo, maintained significant above normal snowpack at 193 percent of median.**  
Photo By: Karl Wetlaufer

**REMINDER:** We are soliciting field work photos from the field again this year. Each month we will pick one to grace the cover of this report! Please include information on where, when and of who/what the photo was taken.

The U.S. Department of Agriculture (USDA) prohibits discrimination against its customers. If you believe you experienced discrimination when obtaining services from USDA, participating in a USDA program, or participating in a program that receives financial assistance from USDA, you may file a complaint with USDA. Information about how to file a discrimination complaint is available from the Office of the Assistant Secretary for Civil Rights. USDA prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex (including gender identity and expression), marital status, familial status, parental status, religion, sexual orientation, political beliefs, genetic information, reprisal, or because all or part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) To file a complaint of discrimination, complete, sign, and mail a program discrimination complaint form, available at any USDA office location or online at [www.ascr.usda.gov](http://www.ascr.usda.gov) or write to: USDA Office of the Assistant Secretary for Civil Rights 1400 Independence Avenue, SW. Washington, DC 20250-9410. Or call toll free at (866) 632-9992 (voice) to obtain additional information, the appropriate office or to request documents. Individuals who are deaf, hard of hearing, or have speech disabilities may contact USDA through the Federal Relay service at (800) 877-8339 or (800) 845-6136 (in Spanish). USDA is an equal opportunity provider, employer, and lender. Persons with disabilities who require alternative means for communication of program information (e.g., Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

# Colorado Statewide Water Supply Conditions for May 1st

## Summary

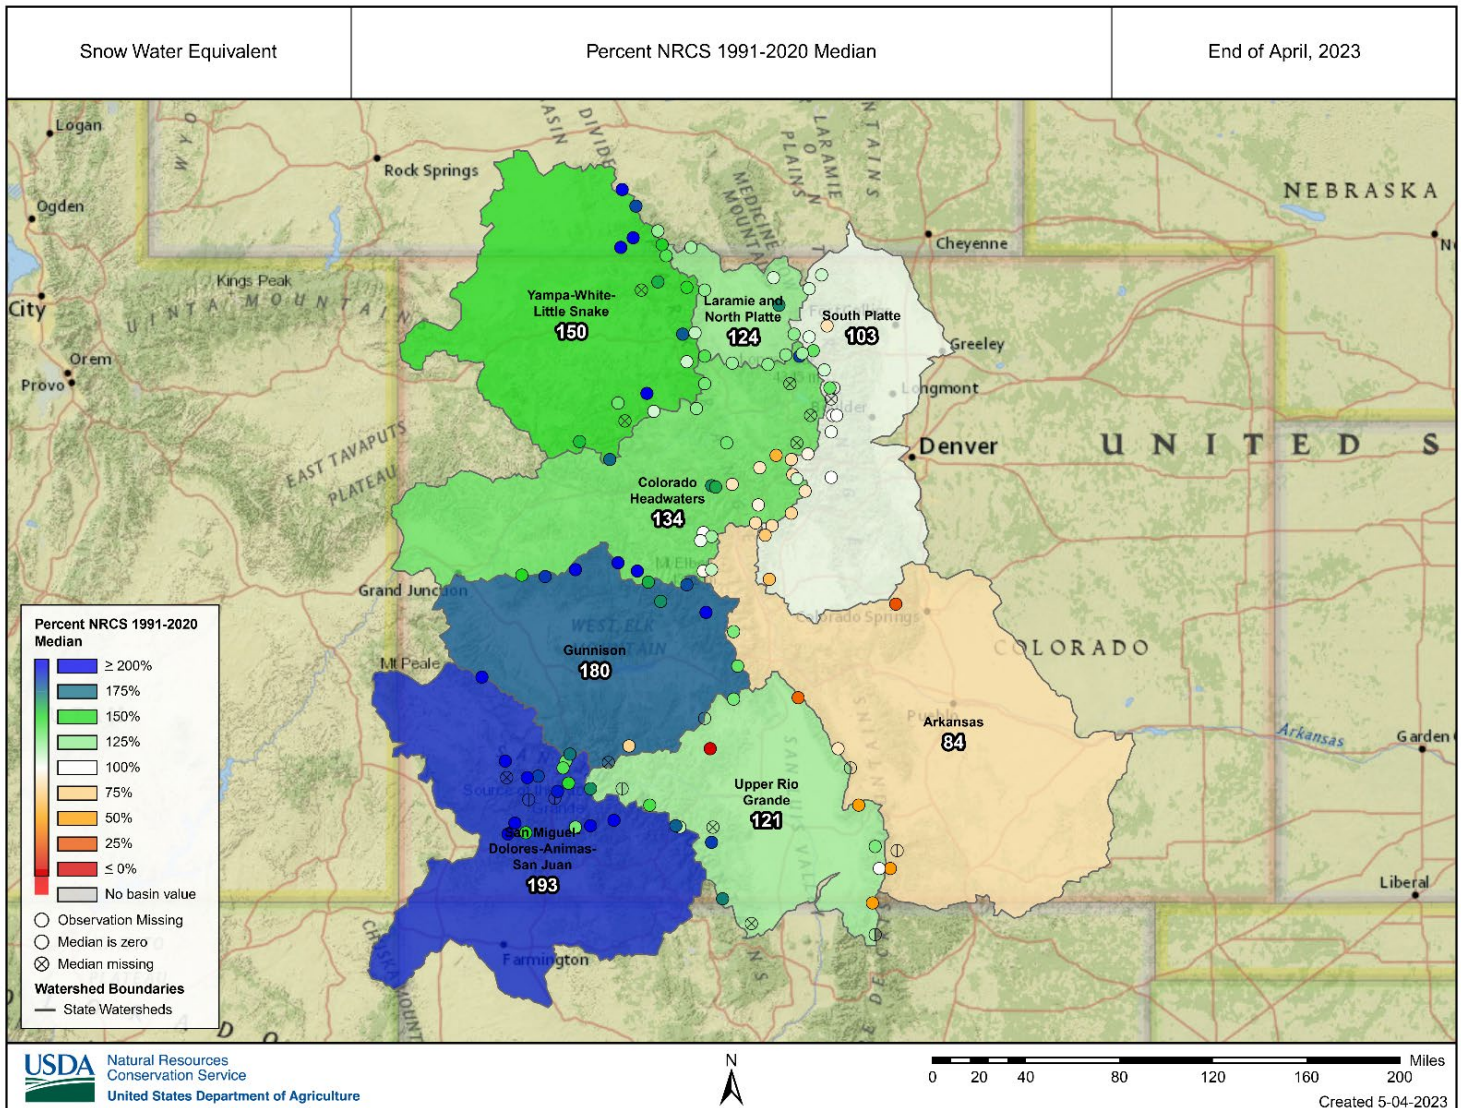

\*For the above graph, snow water equivalent (SWE) values are calculated using daily SNOTEL data only. SWE numbers presented in the text are values from the first of the month and include manual Snow Course measurements along with SNOTEL data.

Despite below average precipitation in April, substantial snowpack remains in river basins near and west of the continental divide. Much of Colorado's above normal water year-to-date precipitation and snowpack was delivered from intense atmospheric rivers that impacted the southwest through much of February and March. Wetter soil conditions from last year's active monsoon season combined with higher snow totals have bolstered streamflow runoff forecasts in the coming months. Intense runoff has already begun in the southwestern parts of the state leading to some localized flooding. East of the divide there is a stark gradient in snowpack totals, from above median snowpack in the northern Front Range to well below median snow totals in the northern Sangre de Cristo Mountains of Colorado. These trends persist despite some moderate precipitation received at the end of April. The Upper Rio Grande and Arkansas River basins above normal basin-wide streamflow is mostly driven from substantial snowpack in the headwater regions of those basins. In contrast, the headwaters of the South Platte River basin in South Park have seen below median snowpack; driving below median runoff volume forecasts in the greater basin. This is despite above median snowpack and forecasted runoff volumes in the northern Front Range. For the Colorado western slope, substantial runoff volumes will help the water supply outlook in Colorado and further downstream, replenishing reservoirs. This is exemplified in southwestern Colorado, where many reservoirs have had significant improvements to reservoir storage as a percent of median over the last month. With substantial snowpack remaining west of the continental divide, flooding will continue to be a concern as snow melt intensifies.

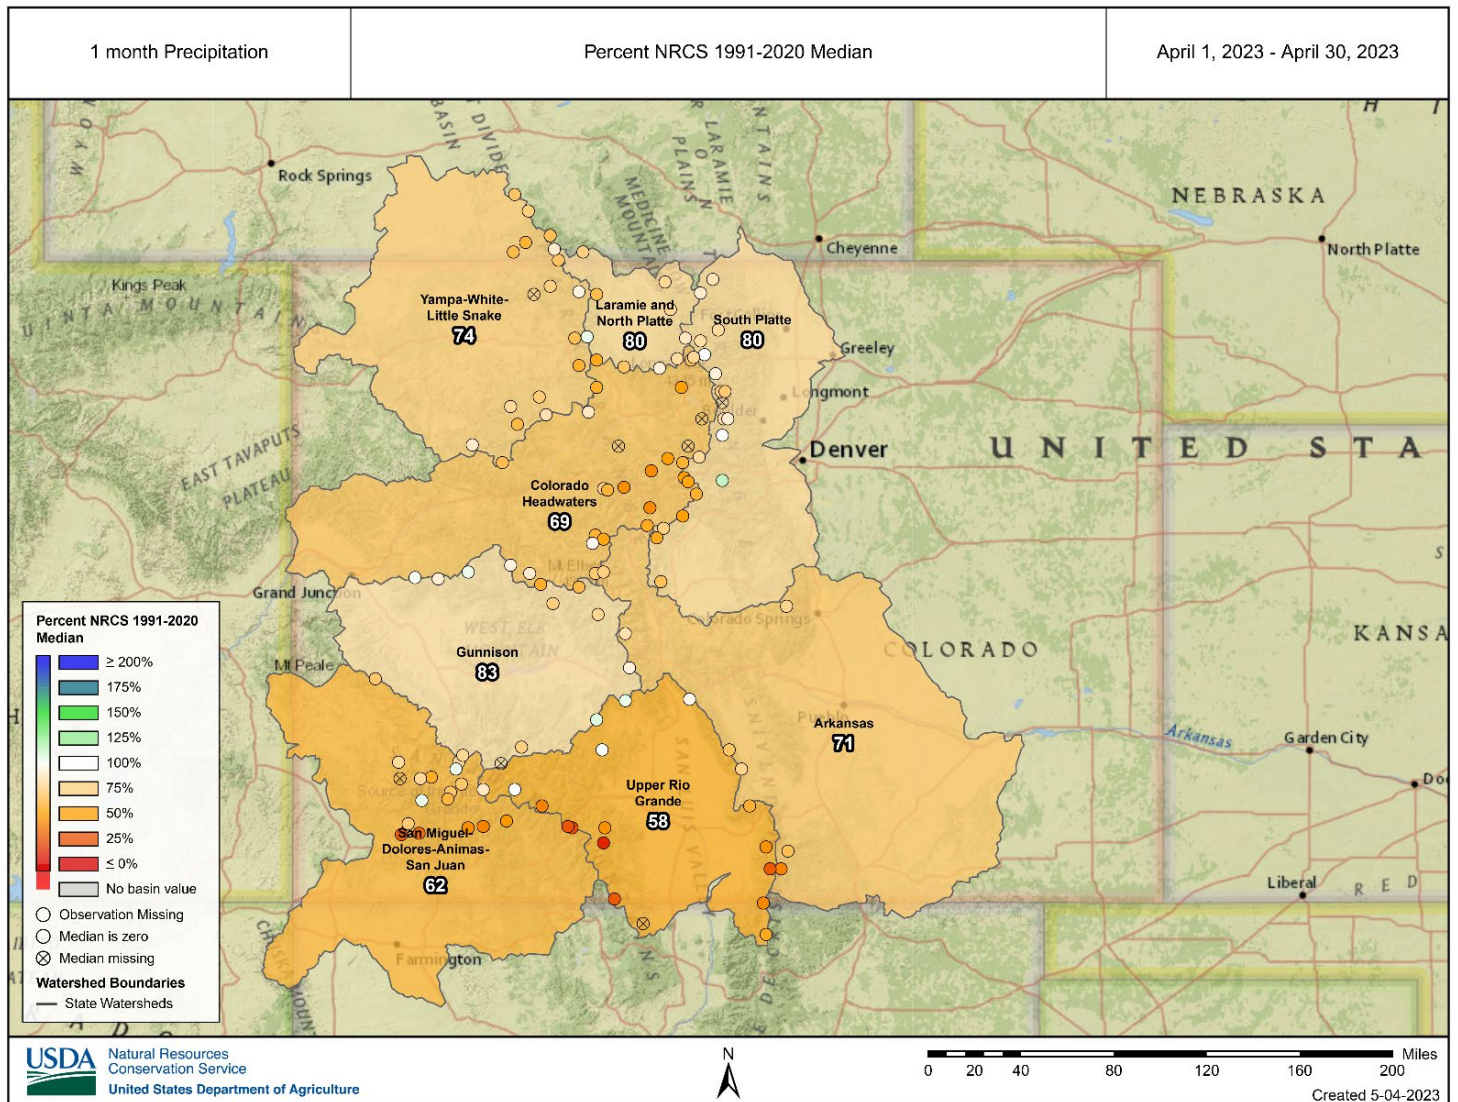

# Snowpack

As spring sets in across the state, snowpack totals remained strong to end April; largely driven by later persistence of lower elevation snowpack. Statewide, stations 10500 feet or above recorded 118 percent of median whereas stations lower than 10500 feet had 152 percent of median snowpack. This pattern is especially apparent in the combined San Miguel-Dolores-Animas-San Juan River basin; stations above 10500 feet ended April with 163 percent of median in contrast to lower elevation stations which ended April at 225 percent of median. In general basins west of the continental divide maintained above normal snowpack ranging from 134 to 193 percent of normal. Due to the large persistent snowpack on the western slope and an increased [chance of above normal temperatures](#) for much of Colorado in the coming months, risks for flooding is a real concern. As of May 1<sup>st</sup>, only the Arkansas river basins had below normal snowpack at 84 percent of normal, largely driven by the northern Sangre de Cristo Mountains which have maintained below normal snowpack most of the water year. Further north the South Platte River basin has a stark gradient where snowpack in the in the headwaters of the South Platte remains below normal compared to above normal snowpack in the northern Front Range. The healthy snowpack in the northern Front Range helps the basin end April with slightly above normal snowpack at 103 percent of median.

# Precipitation

After record precipitation fell in March, all major basins received below normal precipitation during April. Despite below normal precipitation last month, all major basins west of the continental divide maintain above the median water-year-to-date precipitation. Statewide water year-to-date precipitation ended April at 112 percent of median. Eight SNOTEL stations recorded the driest or second driest April on record whereas a month ago, 34 stations recorded record precipitation for March. Despite some late April storms impacting the front range, both the South Platte and Arkansas river basins received below average precipitation at 80 and 71 percent of median, respectively. In general, the least precipitation was received in the combined San Miguel-Dolores-Animas-San and the Upper Rio Grande River basins ending April at 62 and 58 percent of median, respectively. Further north, the Gunnison, Colorado Headwaters, the combined Yampa-White-Little Snake, and the combined Laramie-North Platte ranged from 69 to 83 percent of median. All river basins west of the continental divide maintained above normal water year-to-date precipitation despite the dry April.

# Reservoir Storage

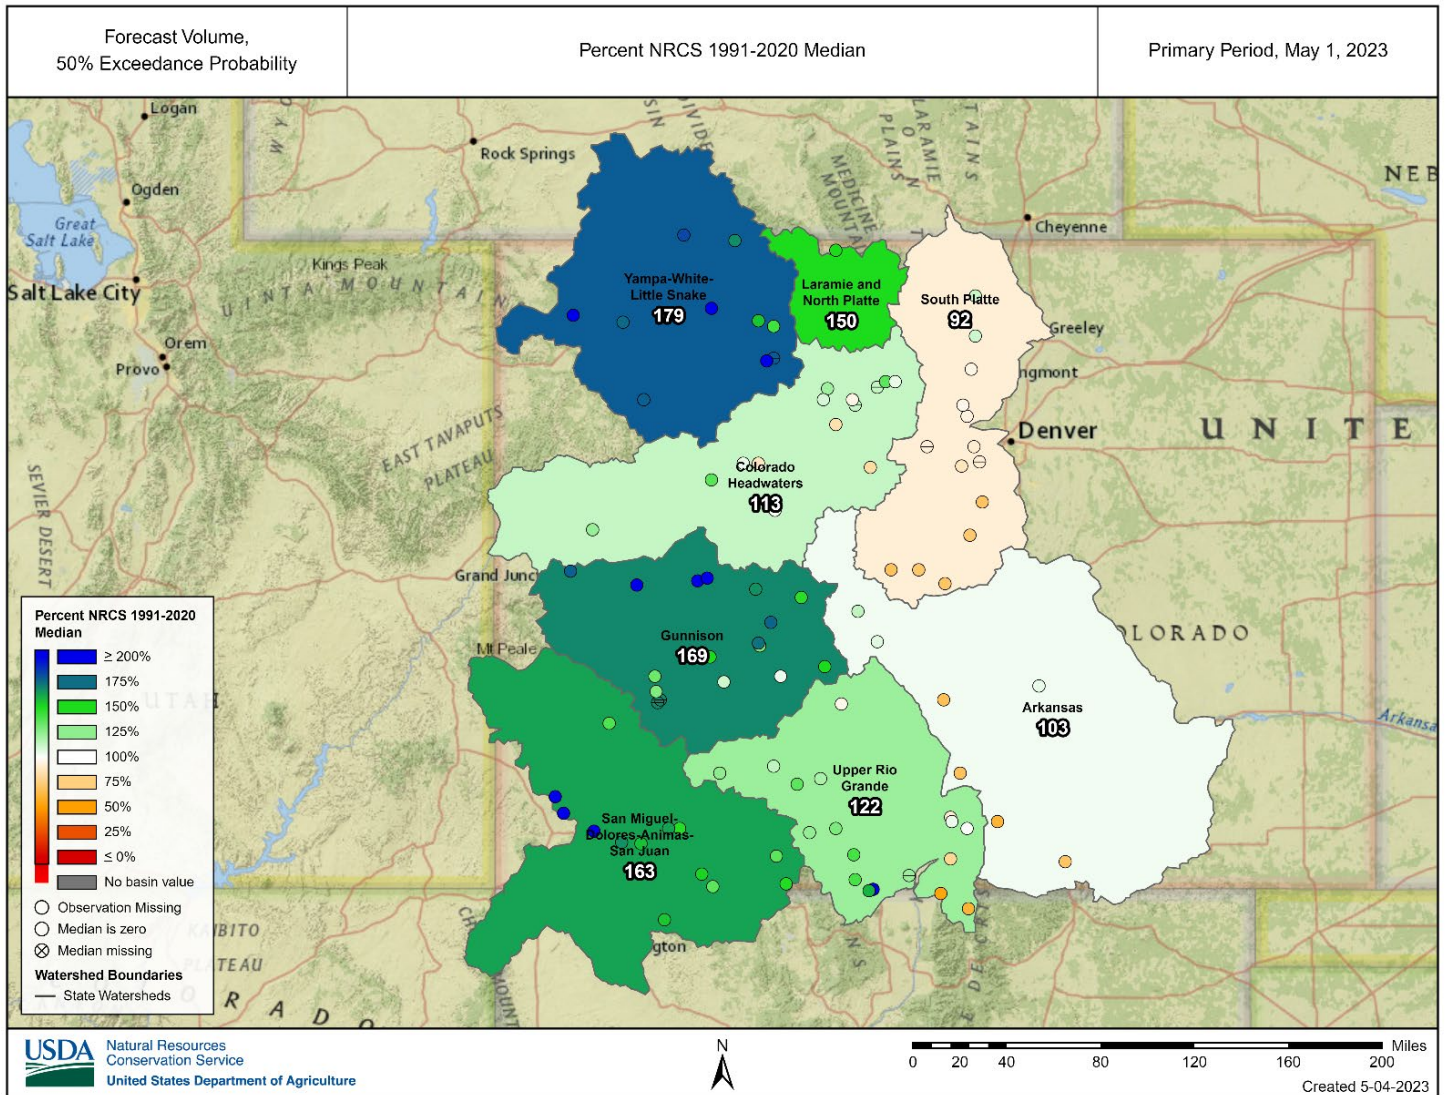

RESERVOIR STORAGE IN COLORADO  
END OF APRIL 2023

Reservoir storage continues to improve over last month, especially in the southwestern regions of Colorado. Currently statewide, reservoir storage sites at 87 percent of median compared to 81 percent of median last month. The combined San Miguel-Dolores-Animas-San Juan and the Gunnison River basins saw the most improvement, ending the month at 82 and 77 percent of normal. Last month those basins held 69 and 71 percent of normal relative storage. Other basins in the state only saw slight changes. The combined Yampa-White-Little Snake and the Colorado Headwaters River basins ended April with 90 and 98 percent of median storage, respectively. East of the continental divide, the Upper Rio Grande, Arkansas, and South Platte held 104, 90 and 94 percent of median reservoir storage, respectively. Compared to this time last year, all major river basins except the South Platte have higher amount of water in storage compared to capacity. As runoff season continues, storage in most basins is expected to increase due to the above normal forecasted runoff volumes in much of the state.

# Streamflow

Due to a drier than normal April, there was a slight decrease in forecasted 50 percent exceedance volumes across the state compared to forecasts last month. Despite the moderation, most of the state is expecting well above median runoff in the coming months. A healthy monsoon and wetter soils going into the water year is helping a persistent above normal snowpack translate into much greater runoff volumes than have been seen in recent years. Only the South Platte River basin is expecting below normal runoff at 92 percent of normal, largely due to the below normal snowpack in the South Platte headwaters. The Arkansas is slightly more optimistic due to the deep snowpack in the upper basin with forecasted 50 percent exceedance volumes at 103 percent of normal. In general, the lower forecasts are seen in rivers draining from the northern Sangre de Cristo and southern Front Range mountains which has seen below normal snowpack most of the water year. In western Colorado streamflow forecasts range from 113 percent of normal in the combined Colorado River basin to a whopping 179 percent of normal in the combined Yampa-White-Little Snake River basin. As the runoff season evolves, flooding could become a major concern in these basins depending on how quickly the snowpack melts and how much additional precipitation is received.

# GUNNISON RIVER BASIN

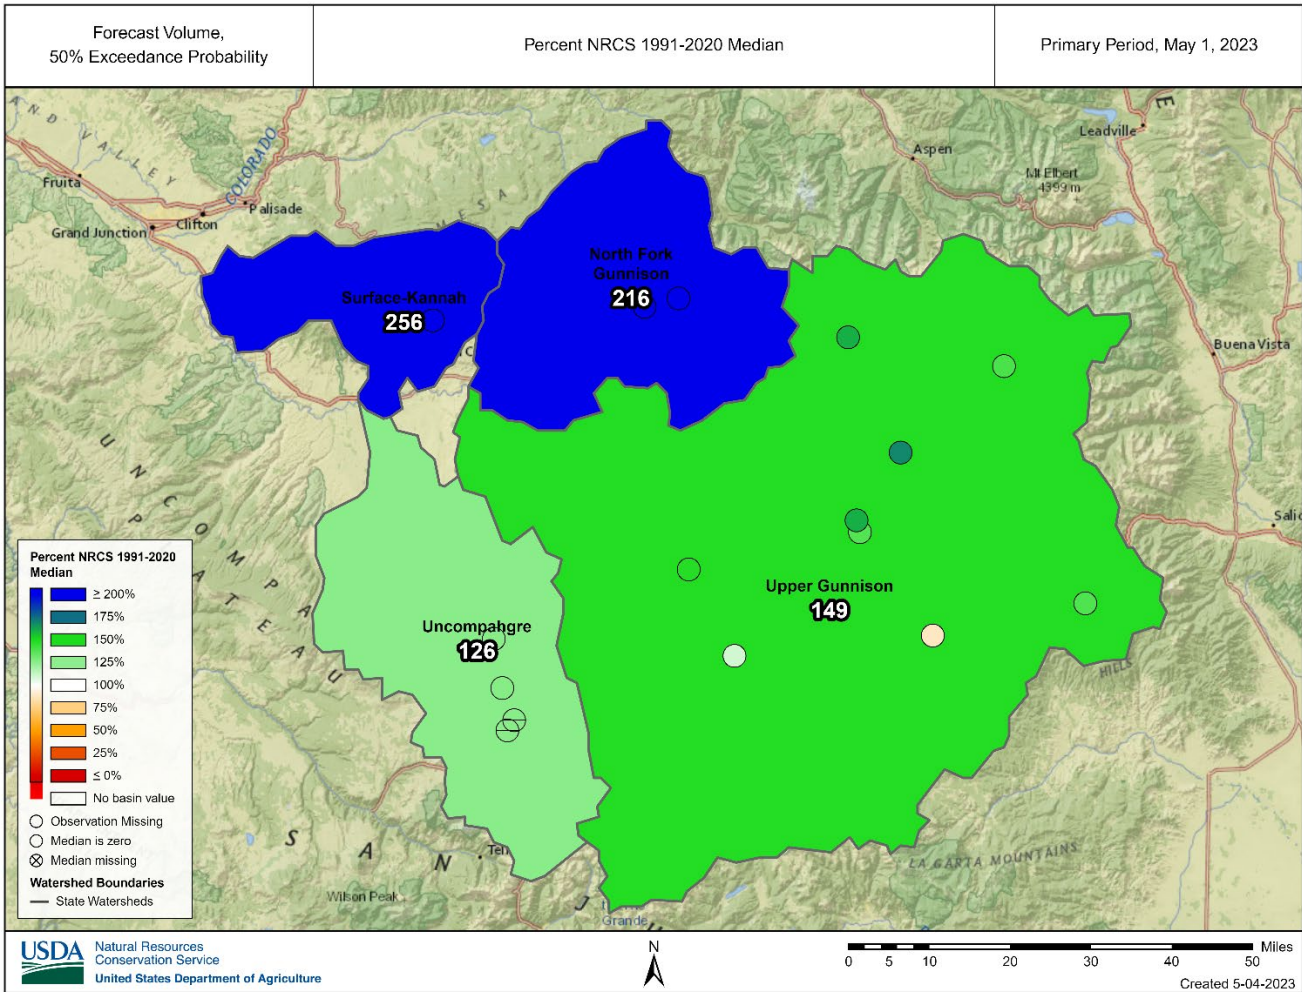

May 1st, 2023

Snowpack in the Gunnison River basin is above normal at 180% of median. Precipitation for April was 83% of median which brings water year-to-date precipitation to 133% of median. Reservoir storage at the end of April was 77% of median compared to 65% last year. Current streamflow forecasts range from 104% of median at Cochetopa Creek below Rock Creek near Parlin to 306% of median at Surface Creek at Cedaredge.

\*Snow water equivalent (SWE) values are calculated using daily SNOTEL data only for the above graph. In the paragraph SWE is calculated for the first of the month using both SNOTEL and Snow Course data.

Gunnison Reservoir Storage Summary for May 1st 2023

## Watershed Snowpack Analysis May 1<sup>st</sup>, 2023

# COLORADO HEADWATERS RIVER BASIN

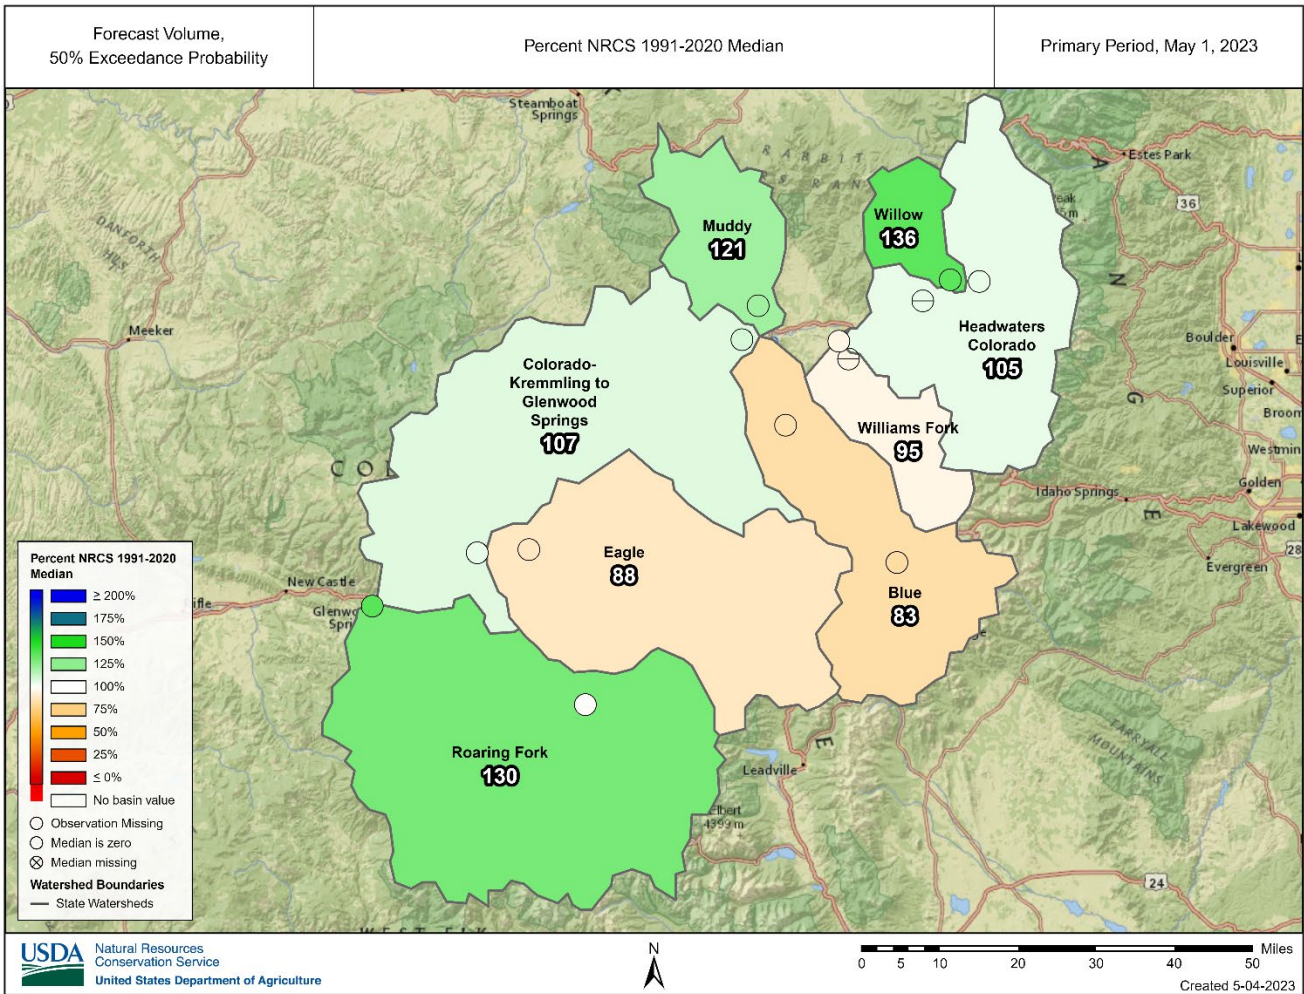

May 1st, 2023

Snowpack in the Colorado River basin is above normal at 134% of the median. Precipitation for April was 69% of median which brings water year-to-date precipitation to 111% of median. Reservoir storage at the end of April was 101% of median compared to 88% last year. Current streamflow forecasts range from 82% of median at Blue River below Dillon Reservoir to 137% of median at Roaring Fork at Glenwood Springs.

\*Snow water equivalent (SWE) values are calculated using daily SNOTEL data only for the above graph. In the paragraph SWE is calculated for the first of the month using both SNOTEL and Snow Course data.

Colorado Headwaters Reservoir Storage Summary for May 1st 2023

## Watershed Snowpack Analysis May 1<sup>st</sup>, 2023

Colorado Headwaters Sub-Basin Snow Data

	# of Sites	% Median	Last Year % Median
Headwaters Colorado	8.0	103.1	76.6
Roaring Fork	12.0	127.2	84.7
Colorado-Kremmling to Glenwood Springs	5.0	151.2	81.0
Eagle	8.0	106.6	93.4

# SOUTH PLATTE RIVER BASIN

May 1st, 2023

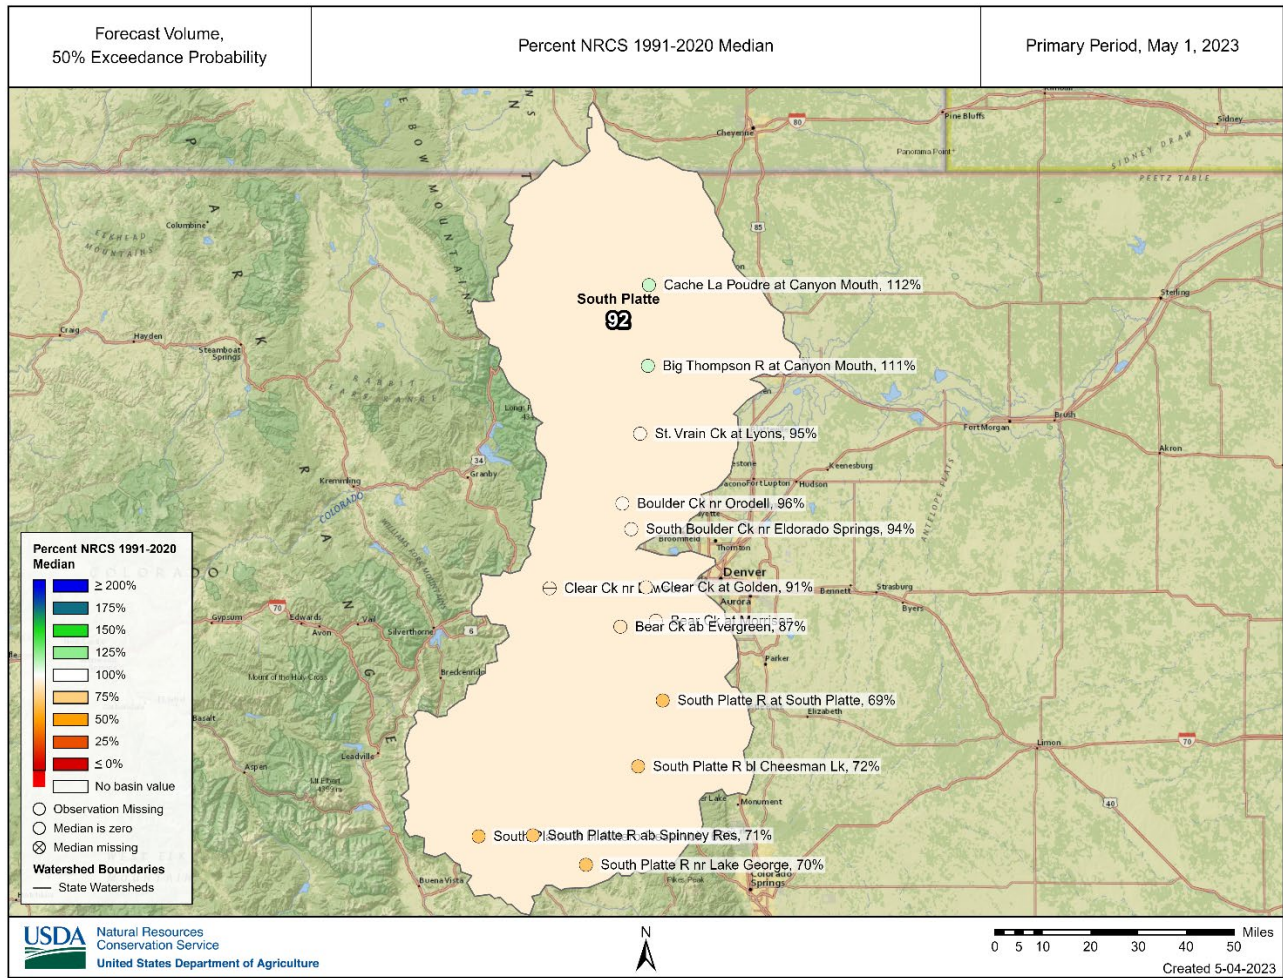

Snowpack in the South Platte River basin is above normal at 103% of median. Precipitation for April was 80% of median which brings water year-to-date precipitation to 93% of median. Reservoir storage at the end of April was 94% of median compared to 100% last year. Current streamflow forecasts are at 92 percent of median and range from 68% of median at South Platte River below Antero Reservoir to 112% of median at Cache La Poudre River at Canyon Mouth.

\*Snow water equivalent (SWE) values are calculated using daily SNOTEL data only for the above graph. In the paragraph SWE is calculated for the first of the month using both SNOTEL and Snow Course data.

South Platte Reservoir Storage Summary for May 1st 2023

\* As of this publication we are still missing data from several reservoirs. Please see website for updates.

## Watershed Snowpack Analysis May 1<sup>st</sup>, 2023

South Platte Sub-Basin Snow Data

# YAMPA-WHITE-LITTLE SNAKE AND LARAMIE-NORTH PLATTE RIVER BASINS

May 1st, 2023

Snowpack in the Yampa-White-Little Snake and the Laramie-North Platte River basins are above normal at 150% and 124% of the median. Precipitation for April was 74% and 80% of median and water year-to-date precipitation is 122% and 111% of median, respectively. Reservoir storage at the end of April for the Yampa-White-Little Snake was 97% of median compared to 77% last year. Current streamflow forecasts range from 142% of median at Yampa River at Steamboat Springs to 248% of median at Little Snake River near Lily.

Some forecasts may be for volumes that are regulated or influenced by diversions and water management.

# New 1991-2020 Statistical Normals

The NRCS Snow Survey and Water Supply Forecasting (SSWSF) Program recently published new statistical normals (medians or averages) to describe the central tendency of a data record over a 30-year period. Data normals are key in helping water users compare current conditions to past conditions using the metric “% of normal.” Every 10 years, the SSWSF Program updates the 30-year normals reference period to stay consistent with World Meteorological Organization standards that account for changing climatic conditions over time. As such, this year the SSWSF Program transitioned from using 1981-2010 data normals to using 1991-2020 data normals.

For the 1991-2020 reference period, the median is the official NRCS normal when conveying information about current snowpack, precipitation, and water supply conditions. The median was previously used as the official 1981-2010 normal for SWE and some streamflow forecast points, but the average was used for other data types. Setting the official normal to the median provides consistency across data types and stations. Viewing the 30-year average December be preferable over the median in some instances, therefore, both the average and the median are available in most NRCS reports and products. See Median vs. Average for more information about the median.

A new suite of statistics for automated snow monitoring stations are available to provide information about normal seasonal snowpack characteristics. These new seasonal statistics include medians and averages for the SWE onset date and melt-out date, as well as the median and average maximum seasonal SWE value (Peak SWE) and date of Peak SWE. More detailed information on the updated normals can be found on the Water and Climate Center’s [30-year normals page](#).

# How to Read Snowpack Graphs

The graphs show snow water equivalent (SWE) (in inches), using daily SNOTEL data. for the October 1 through September 30 water year. Basin “observed” SWE values are computed using SNOTEL sites which are characteristic of the snowpack of the particular basin.

**Current** water year is represented by the heavy red line terminating on the last day the graphic was updated.

**Historical** observed percentile range is shown as a gray background area on the graph. Shades of gray indicate maximum, 90 percentile, 70 percentile, 50 percentile (solid black line), 30 percentile, 10 percentile, and minimum for the period of record.

**50 % Exceedance Projection:** The most probabilistic snowpack projection, based on the median snowpack is projected forward from the end of the current period to the end of the current water year.

---

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation, antecedent streamflow, and indices of the El Niño / Southern Oscillation are used in computerized statistical and simulation models to prepare runoff forecasts. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

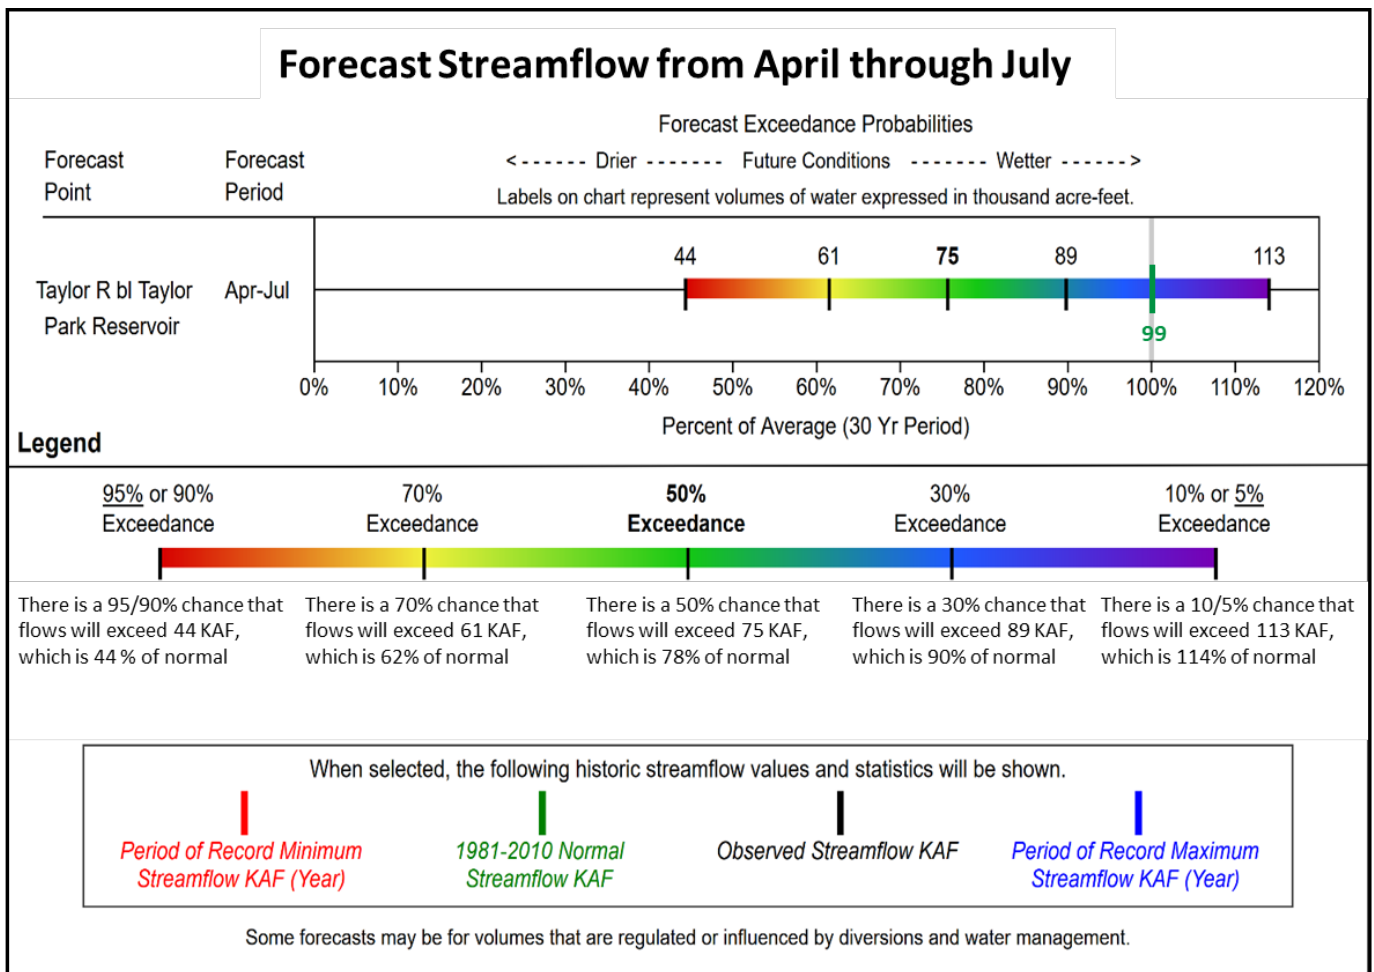

The wider the spread among these values, the more uncertain the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they December want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they December want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

---

# Interpreting the Forecast Graphics

These graphics provide a new way to visualize the range of streamflows represented by the forecast exceedance probabilities for each forecast period. The colors in the bar for each forecast point indicate the exceedance probability of the forecasts and the vertical lines on the bar signify the five published forecast exceedance probabilities. The numbers displayed above the color scale represent the actual forecasted streamflow volume (in KAF) for the given exceedance probability. The horizontal axis provides the percent of median represented by each forecast and the gray line centered above 100% represents the 1981-2010 historical median streamflow. The position of the gray line relative to the color scale provides a benchmark for considering future streamflows. If the majority of the forecast range is to the right of the gray line, there is a higher likelihood of above median streamflow volumes during the provided forecast period. Conversely, if the majority of the color bar is to the left of the median mark, below median volumes are more likely. The horizontal span of the forecasts offers an indication of the uncertainty in a given forecast: when the bar spans a large horizontal range, the forecast skill is low and uncertainty is high; when the bar is narrow in width, the forecast skill is higher and uncertainty lower.
