

Colorado

Water Supply Outlook Report

June 1st, 2023

Significant dust on snow events from April amplified snowmelt rates this runoff season. This image was captured on May 20th and is of the Headwaters of Brush Creek in the East River watershed and highlights dust on snow layers. These high albedo layers will continue to act as a snowmelt catalyst with the combination of warming spring temperatures.

Photo By: Andrew Briebart

REMINDER: We are soliciting field work photos from the field again this year. Each month we will pick one to grace the cover of this report! Please include information on where, when and of who/what the photo was taken.

The U.S. Department of Agriculture (USDA) prohibits discrimination against its customers. If you believe you experienced discrimination when obtaining services from USDA, participating in a USDA program, or participating in a program that receives financial assistance from USDA, you December file a complaint with USDA. Information about how to file a discrimination complaint is available from the Office of the Assistant Secretary for Civil Rights. USDA prohibits discrimination in all its programs and activities on the basis of race, color, national origin, age, disability, and where applicable, sex (including gender identity and expression), marital status, familial status, parental status, religion, sexual orientation, political beliefs, genetic information, reprisal, or because all or part of an individual's income is derived from any public assistance program. (Not all prohibited bases apply to all programs.) To file a complaint of discrimination, complete, sign, and mail a program discrimination complaint form, available at any USDA office location or online at www.ascr.usda.gov or write to: USDA Office of the Assistant Secretary for Civil Rights 1400 Independence Avenue, SW. Washington, DC 20250-9410. Or call toll free at (866) 632-9992 (voice) to obtain additional information, the appropriate office or to request documents. Individuals who are deaf, hard of hearing, or have speech disabilities December contact USDA through the Federal Relay service at (800) 877-8339 or (800) 845-6136 (in Spanish). USDA is an equal opportunity provider, employer, and lender. Persons with disabilities who require alternative means for communication of program information (e.g., Braille, large print, audiotape, etc.) should contact USDA's TARGET Center at (202) 720-2600 (voice and TDD).

Colorado Statewide Water Supply Conditions for June 1st

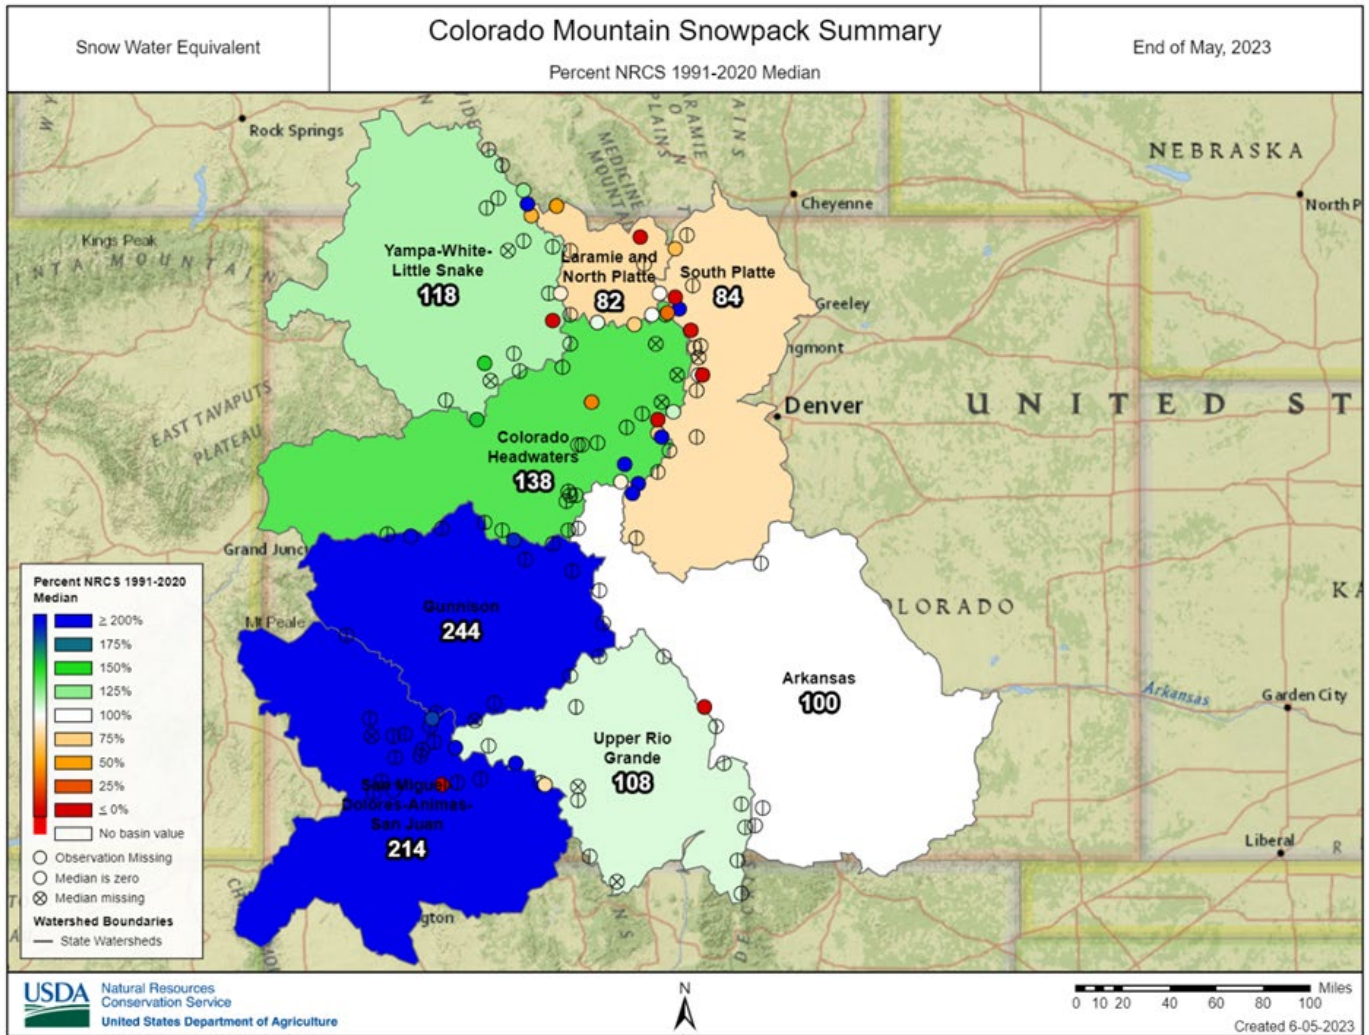

Summary

*For the above graph, snow water equivalent (SWE) values are calculated using daily SNOTEL data only. SWE numbers presented in the text are values from the first of the month and include manual Snow Course measurements along with SNOTEL data.

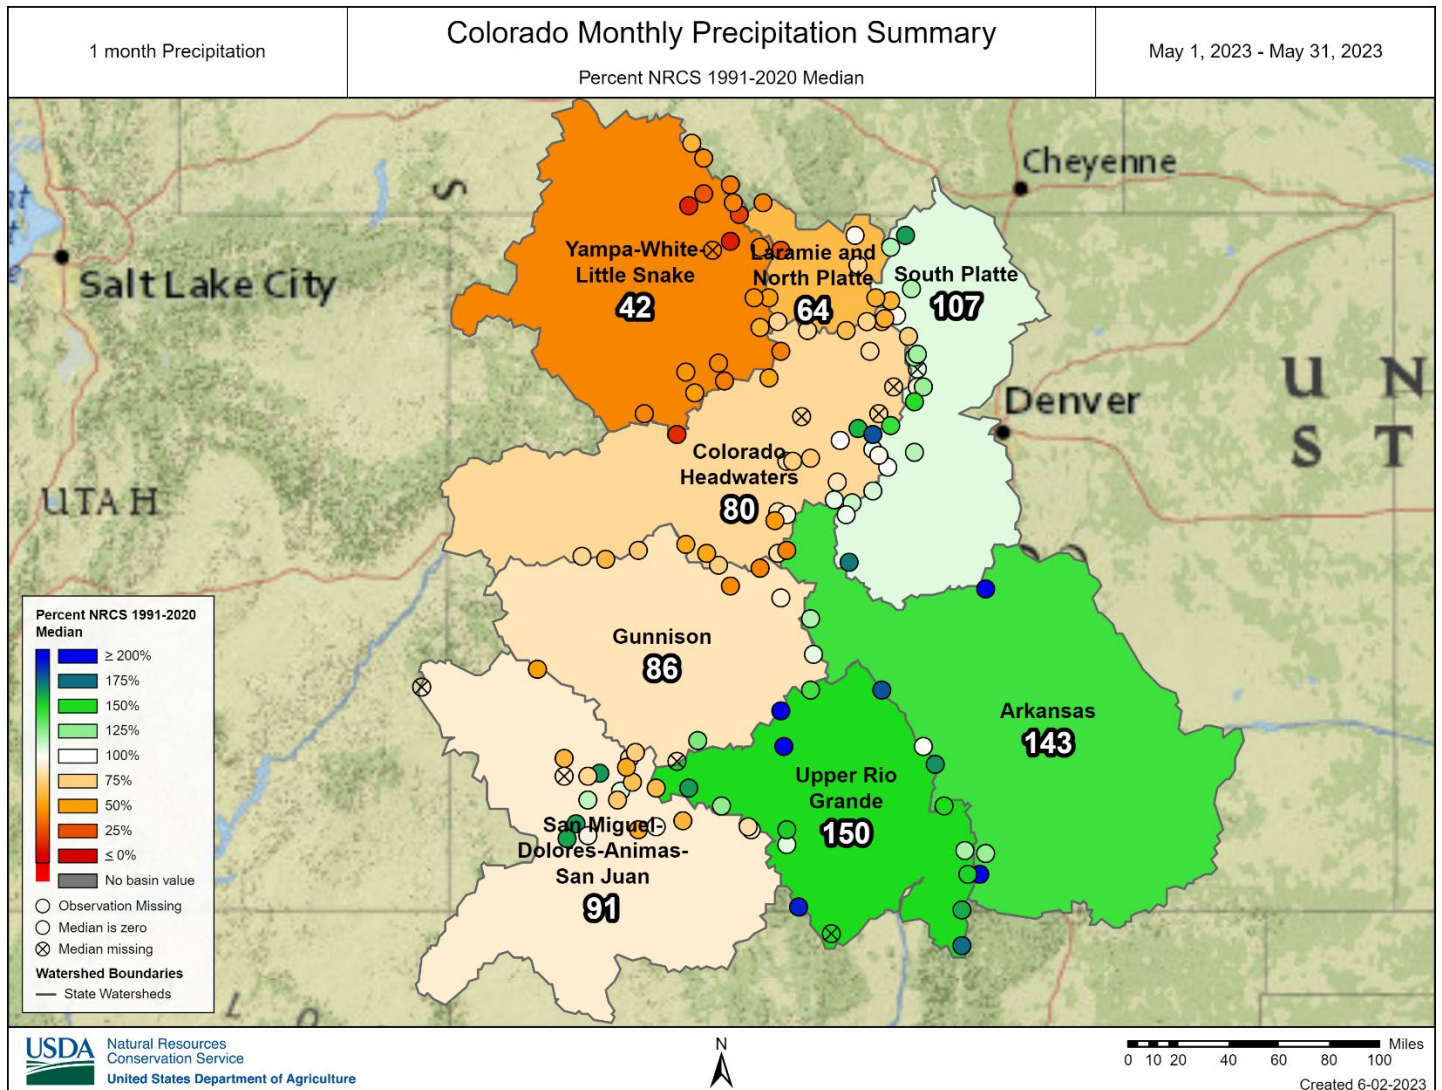

Approximately half of the streamflow forecast points in Colorado measured above the 90th percentile of observed volumetric streamflow in the month of May. Fourteen of these points recorded the highest or second highest streamflow volumes on record for May. These impressive streamflow volumes have helped to boost reservoir storage in some of the basins with the largest deficits bringing statewide reservoir storage back up to normal values for the first time in three years. Precipitation during the month of May strongly favored the Front Range down through the Sangre de Cristo mountains compared to most of Western Colorado. This was a departure from previous trends and helped add more moisture to those areas which had been drier than the Western Slope. Following the statewide well above normal streamflow volumes in May, volumetric forecasts for the June-July period are for a lower percent of normal than the full April-July period. That said, except for the Colorado Headwaters River basin all other major river basins of Western Colorado can anticipate maintaining well above normal streamflow for the next two months. Forecasts are the lowest in the South Platte basin and in particularly along the mainstem headwaters with values increasing in the northern tributaries.

Snowpack

As of June 1st, 67 percent of all SNOTEL stations across Colorado have melted out, and typically only 56 percent of SNOTEL have melted out by this time. Although more SNOTEL sites are melted out than normal, statewide snowpack remains above normal at 122 percent of median; largely benefiting from the remaining deep snowpacks at high elevations on the west slope. As snowmelt-runoff season is in full force, there is a noticeable contrast between river basins east and west of the continental divide. All major river basins on the west slope currently have above normal snowpacks. Peak snowpacks for these basins ranged from a high of 175 percent of median for the combined San Miguel-Dolores-Animas-San Juan River basin to 125 percent of median for the Colorado Headwaters River basin. The major river basins in the western part of the state had the deepest peak snowpacks this winter but also experienced some of the fastest snowmelt rates during May, especially at lower elevations. Above average temperatures and prolific [dust-on-snow](#) contributed to these high melt rates for western river basins. Conversely, the major river basins east of the continental divide currently have near to below normal snowpacks, and peak snowpacks for these basins ranged from a high of 113 percent of median for the Upper Rio Grande River basin to 85 percent of median for the Arkansas River basin. During May, consistently active storm patterns brought cooler temperatures and more precipitation to river basins east of the Continental Divide contributing to slower snowmelt rates. Overall, there is still substantial snow at high elevations across much of the state, which will continue to contribute to the runoff season.

Precipitation

May brought wet conditions to eastern basins with spring storms heavily favoring the South Platte, Arkansas and Upper Rio Grande. Eastern basins received above normal precipitation while western basins were below normal, with the Yampa-White-Little Snake and Laramie-North Platte having received the lowest totals. Statewide precipitation is at 110 percent of median. Water year-to-date, precipitation is above normal for most of the state and almost near normal in the South Platte and Arkansas at 94 percent of median and 95 percent of median, respectively. Due to drier trends carrying into May, ten SNOTELs were at record dry levels in the northwest portion of the state over the last month. Looking at the bigger water picture, water year-to-date precipitation at these same SNOTELs are above normal. Monthly dry patterns in northwest basins may likely improve based on current outlooks. Statewide a below normal temperature outlook and above normal precipitation [outlook](#) is expected for June. NOAA has also forecasted “likely above” precipitation in the northwestern portion of the state and may likely increase precipitation in the Yampa-White-Little Snake and Laramie-North Platte basins. [Drought conditions](#) are not present for most of the state, and where present, for roughly 6% of the state and generally east of the Divide, drought will likely improve or may be removed with current [outlook](#) conditions.

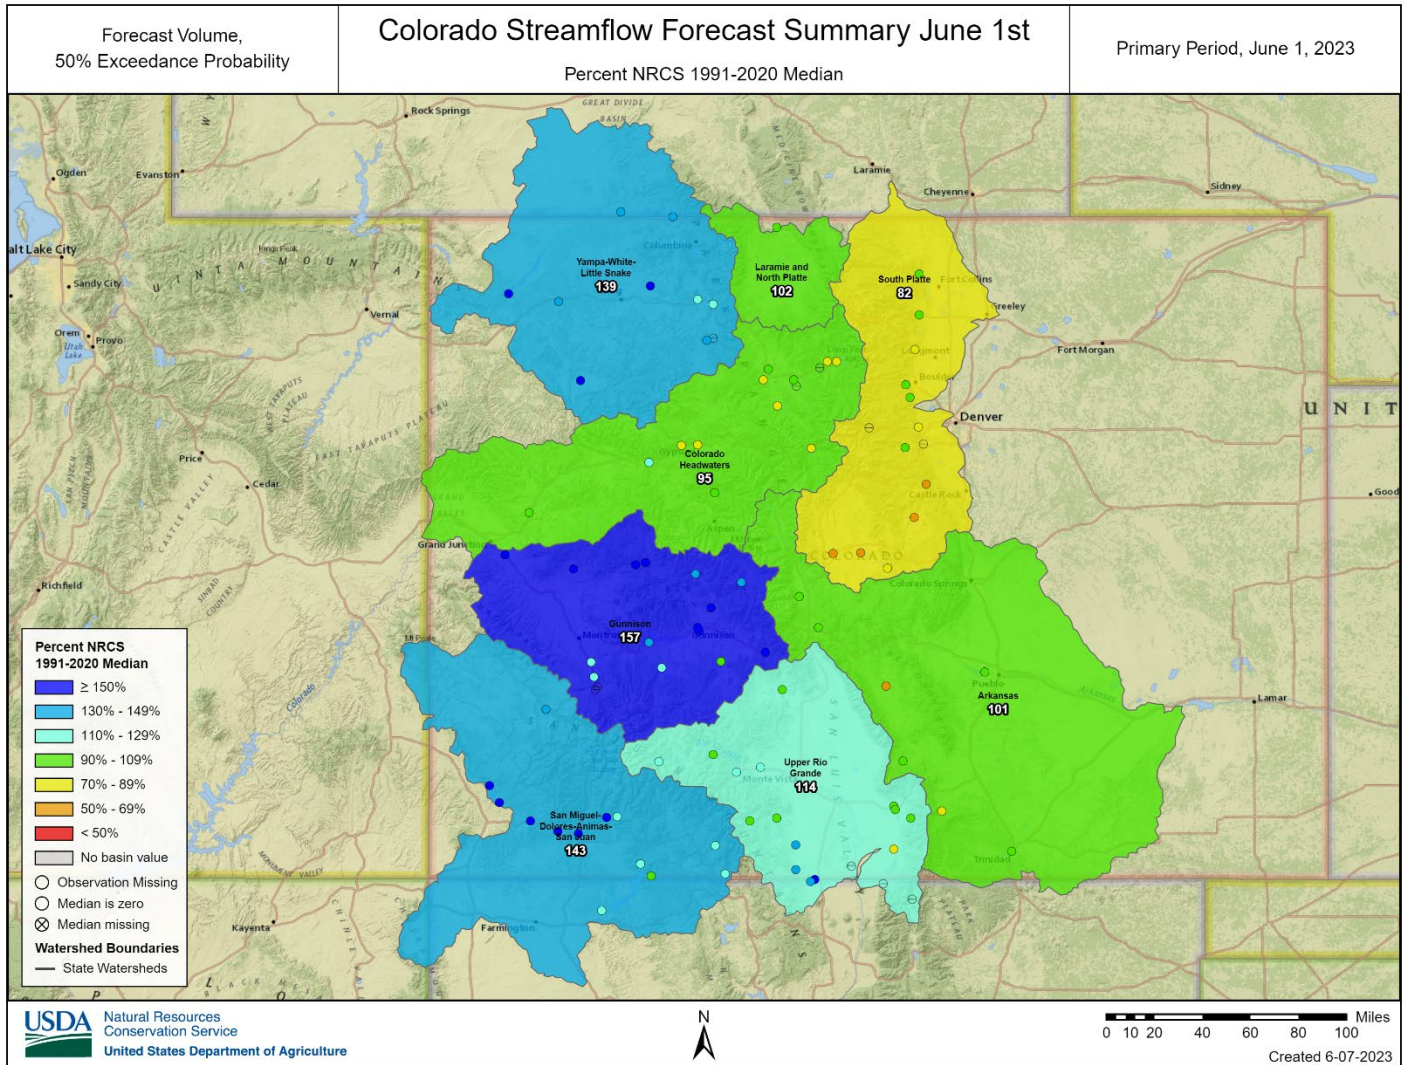

Reservoir Storage

RESERVOIR STORAGE IN COLORADO
END OF MAY 2023

Statewide reservoir storage is at 100 percent of normal compared to 80 percent of normal this time last year. All basin storage readings are above or near normal ranging from 92 percent of median in the combined San Miguel-Dolores-Animas-San Juan River basin to 124 percent of median in the Upper Rio Grande River basin. Month-to-date, the biggest improvements are in the Gunnison River basin currently at 100 percent of normal and in the San Miguel-Dolores-Animas-San Juan basins. A combination of warm temperatures, rain on snow events, and [dust on snow](#) layers accelerated runoff rates. However, recent snow events have decreased albedo and decreased runoff rates, particularly in sub-basins above 10,000 ft in the San Juans and Colorado River Basin. “Even with rapid early melt, large snow years can result in much higher percent of normal runoff later in the season, particularly in basins that typically don’t have large runoff volumes in June-July” – Angus Goodbody, Hydrologist, USDA-NRCS National Water and Climate Center. As the still very abundant snowpack continues to melt and with the addition of upcoming precipitation we should see an increase in already above normal storage readings basin wide.

Streamflow

Consistent warm temperatures have started to melt away this seasons deep snowpack, which has allowed for some streamflows to already reach peak discharge. The gage at Yampa River near Maybell recorded peak runoff on May 17th at 15400 cfs. The Gunnison River near Grand Junction peak discharge was at 16900 cfs and the Colorado River near Cameo peaked towards the end of the month around 16700 cfs. Due to a lower seasonal snowpack, forecasts in the South Platte are below normal at 82 percent of median. All other forecasts are near or well above normal ranging from 95 percent of median in the Colorado River Basin to 156 percent of median in the Gunnison. Late spring storms have also bolstered streamflow rates with recent precipitation events favoring eastern basins. The Denver Metro saw upwards of 7" of precipitation ranking May as the fifth highest moisture month on record. Recent storms, particularly in the Colorado River basin and San Juans have temporarily slowed down snowmelt through cooler temperatures and precipitation. As we move into June, warmer temperatures will continue to gradually melt away the remaining snowpack at higher elevations and any additional precipitation events should bolster runoff. No major river [flooding](#) is currently expected.

GUNNISON RIVER BASIN

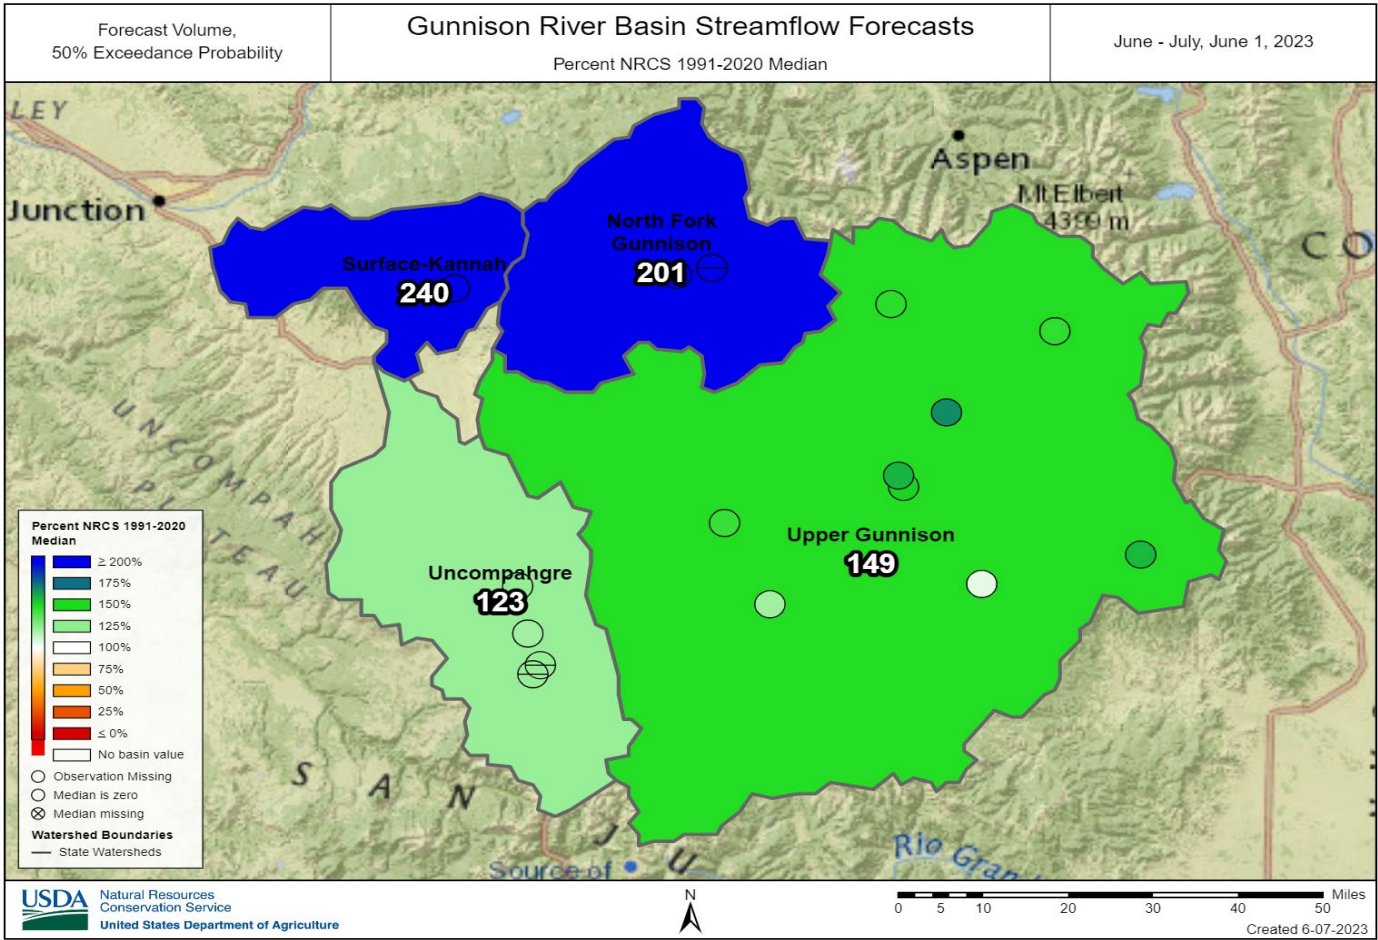

June 1st, 2023

Snowpack in the Gunnison River basin is above normal at 244% of median. Precipitation for May was 86% of median which brings water year-to-date precipitation to 129% of median. Reservoir storage at the end of May was 100% of median compared to 70% last year. Current streamflow forecasts range from 106% of median at Cochetopa Creek below Rock Creek near Parlin to 240% of median at Surface Creek at Cedaredge.

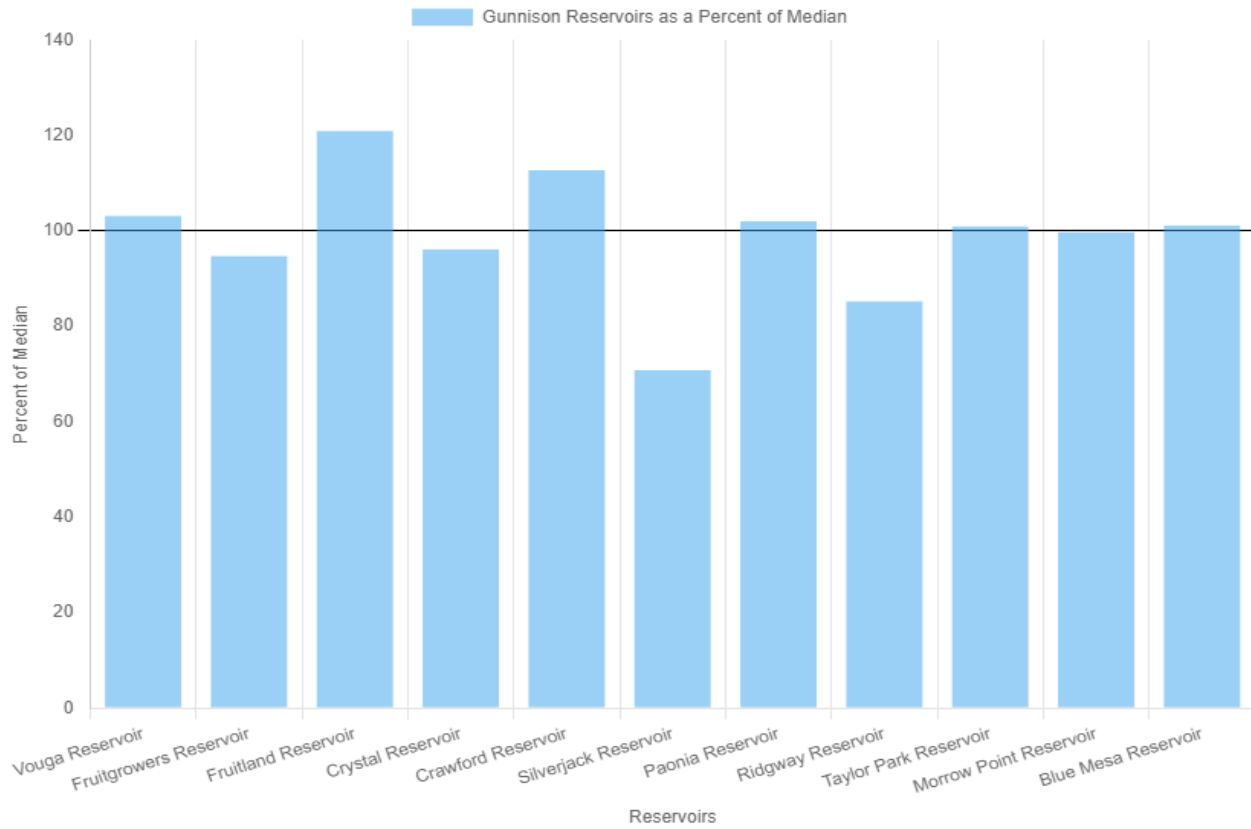

*Snow water equivalent (SWE) values are calculated using daily SNOTEL data only for the above graph. In the paragraph SWE is calculated for the first of the month using both SNOTEL and Snow Course data.

Some forecasts may be for volumes that are regulated or influenced by diversions and water management.

COLORADO HEADWATERS RIVER BASIN

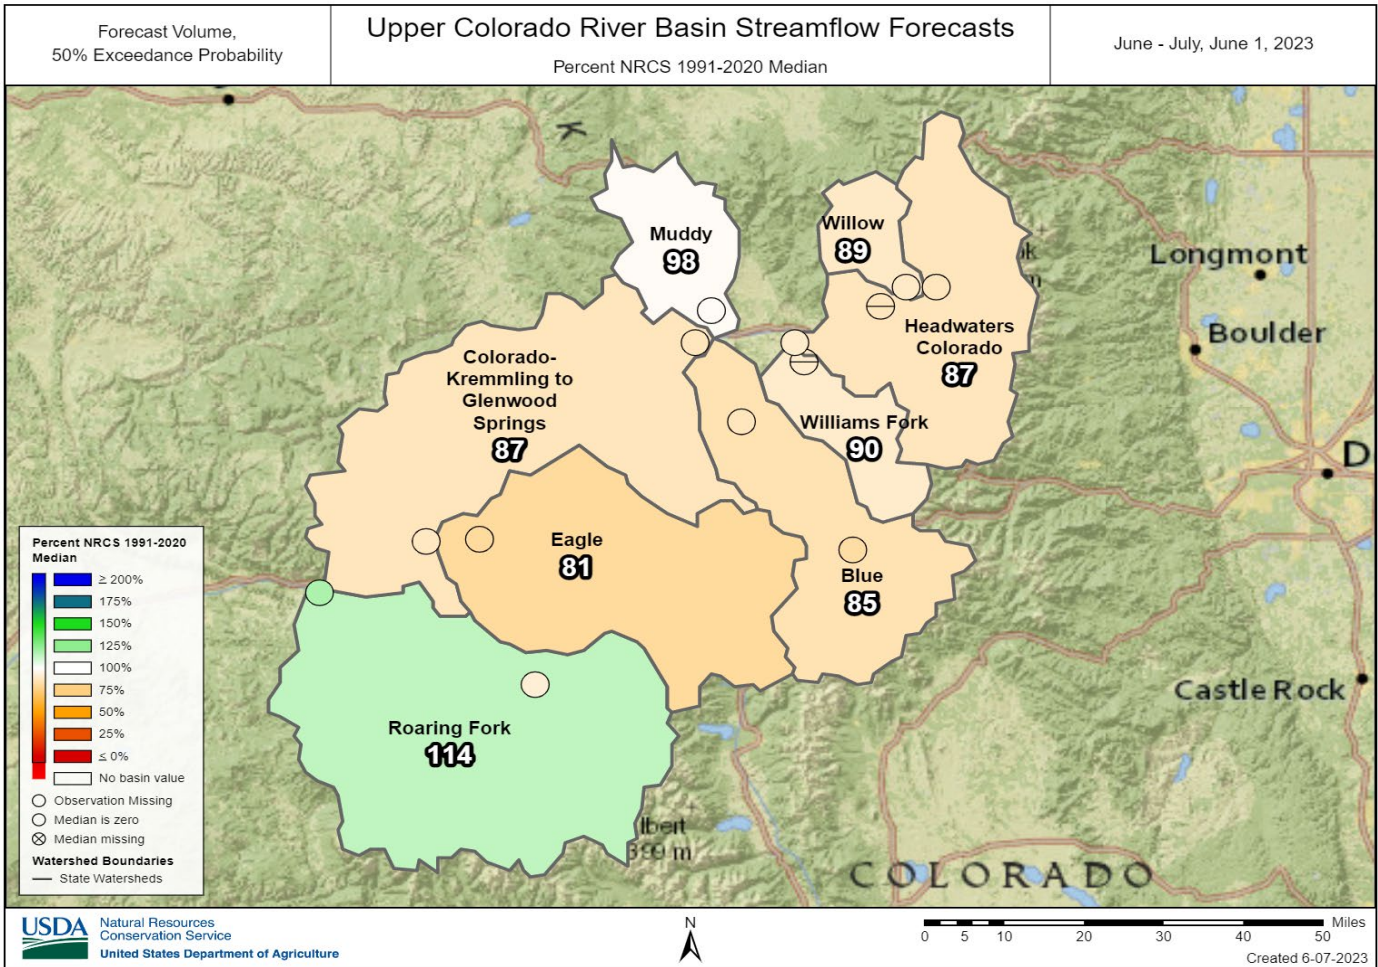

June 1st, 2023

Snowpack in the Colorado River basin is above normal at 138% of the median. Precipitation for May was 80% of median which brings water year-to-date precipitation to 108% of median. Reservoir storage at the end of May was 110% of median compared to 97% last year. Current streamflow forecasts range from 81% of median at Eagle River below Gypsum to 118% of median at Roaring Fork at Glenwood Springs.

*Snow water equivalent (SWE) values are calculated using daily SNOTEL data only for the above graph. In the paragraph SWE is calculated for the first of the month using both SNOTEL and Snow Course data.

Colorado Headwaters Reservoir Storage Summary for June 1st 2023

New 1991-2020 Statistical Normals

The NRCS Snow Survey and Water Supply Forecasting (SSWSF) Program recently published new statistical normals (medians or averages) to describe the central tendency of a data record over a 30-year period. Data normals are key in helping water users compare current conditions to past conditions using the metric “% of normal.” Every 10 years, the SSWSF Program updates the 30-year normals reference period to stay consistent with World Meteorological Organization standards that account for changing climatic conditions over time. As such, this year the SSWSF Program transitioned from using 1981-2010 data normals to using 1991-2020 data normals.

For the 1991-2020 reference period, the median is the official NRCS normal when conveying information about current snowpack, precipitation, and water supply conditions. The median was previously used as the official 1981-2010 normal for SWE and some streamflow forecast points, but the average was used for other data types. Setting the official normal to the median provides consistency across data types and stations. Viewing the 30-year average December be preferable over the median in some instances, therefore, both the average and the median are available in most NRCS reports and products. See Median vs. Average for more information about the median.

A new suite of statistics for automated snow monitoring stations are available to provide information about normal seasonal snowpack characteristics. These new seasonal statistics include medians and averages for the SWE onset date and melt-out date, as well as the median and average maximum seasonal SWE value (Peak SWE) and date of Peak SWE. More detailed information on the updated normals can be found on the Water and Climate Center’s [30-year normals page](#).

How to Read Snowpack Graphs

The graphs show snow water equivalent (SWE) (in inches), using daily SNOTEL data. for the October 1 through September 30 water year. Basin “observed” SWE values are computed using SNOTEL sites which are characteristic of the snowpack of the particular basin.

Current water year is represented by the heavy red line terminating on the last day the graphic was updated.

Historical observed percentile range is shown as a gray background area on the graph. Shades of gray indicate maximum, 90 percentile, 70 percentile, 50 percentile (solid black line), 30 percentile, 10 percentile, and minimum for the period of record.

50 % Exceedance Projection: The most probabilistic snowpack projection, based on the median snowpack is projected forward from the end of the current period to the end of the current water year.

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when it melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation, antecedent streamflow, and indices of the El Niño / Southern Oscillation are used in computerized statistical and simulation models to prepare runoff forecasts. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind, of course, are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertain the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they December want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they December want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

Interpreting the Forecast Graphics

These graphics provide a new way to visualize the range of streamflows represented by the forecast exceedance probabilities for each forecast period. The colors in the bar for each forecast point indicate the exceedance probability of the forecasts and the vertical lines on the bar signify the five published forecast exceedance probabilities. The numbers displayed above the color scale represent the actual forecasted streamflow volume (in KAF) for the given exceedance probability. The horizontal axis provides the percent of median represented by each forecast and the gray line centered above 100% represents the 1981-2010 historical median streamflow. The position of the gray line relative to the color scale provides a benchmark for considering future streamflows. If the majority of the forecast range is to the right of the gray line, there is a higher likelihood of above median streamflow volumes during the provided forecast period. Conversely, if the majority of the color bar is to the left of the median mark, below median volumes are more likely. The horizontal span of the forecasts offers an indication of the uncertainty in a given forecast: when the bar spans a large horizontal range, the forecast skill is low and uncertainty is high; when the bar is narrow in width, the forecast skill is higher and uncertainty lower.

In addition to the water supply outlook reports, water supply forecast information for the Western United States is available from the Natural Resources Conservation Service and the National Weather Service monthly, February through June. The information December be obtained from the Natural Resources Conservation Service web page at <http://www.wcc.nrcs.usda.gov/wsf/westwide.html>
