Idaho Water Supply Outlook Report

April 1, 2023

New record SWE set at the Pebble Creek SNOTEL & Snow Course for April 1 (photo by Cameron Williams, 3/28/2023).

Pebble Creek SNOTEL site was installed in 2021 to expand snow monitoring in the Willow-Blackfoot-Portneuf basin. SNOTEL sites are often installed near existing snow courses so that the new data can be used right away in snow runoff forecasting. Measurements have been made at this snow course for 78 years and a new record was set this month with 87" depth and 29.5" SWE. Although we are excited that drought-stricken areas are finally getting relief, these large amounts of snow could lead to flooding in places if melting occurs too quickly this spring.

How forecasts are made

Most of the annual streamflow in the western United States originates as snowfall that has accumulated in the mountains during the winter and early spring. As the snowpack accumulates, hydrologists estimate the runoff that will occur when the snow melts. Measurements of snow water equivalent at selected manual snow courses and automated SNOTEL sites, along with precipitation, antecedent streamflow, and indices of the El Niño / Southern Oscillation are used in computerized statistical and simulation models to produce runoff forecasts. Unless otherwise specified, all forecasts are for flows that would occur naturally without any upstream influences.

Forecasts of any kind are not perfect. Streamflow forecast uncertainty arises from three primary sources: (1) uncertain knowledge of future weather conditions, (2) uncertainty in the forecasting procedure, and (3) errors in the data. The forecast, therefore, must be interpreted not as a single value but rather as a range of values with specific probabilities of occurrence. The middle of the range is expressed by the 50% exceedance probability forecast, for which there is a 50% chance that the actual flow will be above, and a 50% chance that the actual flow will be below, this value. To describe the expected range around this 50% value, four other forecasts are provided, two smaller values (90% and 70% exceedance probability) and two larger values (30%, and 10% exceedance probability). For example, there is a 90% chance that the actual flow will be more than the 90% exceedance probability forecast. The others can be interpreted similarly.

The wider the spread among these values, the more uncertainty is in the forecast. As the season progresses, forecasts become more accurate, primarily because a greater portion of the future weather conditions become known; this is reflected by a narrowing of the range around the 50% exceedance probability forecast. Users should take this uncertainty into consideration when making operational decisions by selecting forecasts corresponding to the level of risk they are willing to assume about the amount of water to be expected. If users anticipate receiving a lesser supply of water, or if they wish to increase their chances of having an adequate supply of water for their operations, they may want to base their decisions on the 90% or 70% exceedance probability forecasts, or something in between. On the other hand, if users are concerned about receiving too much water (for example, threat of flooding), they may want to base their decisions on the 30% or 10% exceedance probability forecasts, or something in between. Regardless of the forecast value users choose for operations, they should be prepared to deal with either more or less water. (Users should remember that even if the 90% exceedance probability forecast is used, there is still a 10% chance of receiving less than this amount.) By using the exceedance probability information, users can easily determine the chances of receiving more or less water.

Starting in 2020, streamflow forecasts with poor prediction skill (jackknife $r^2 < 0.34$) will no longer be issued. This will primarily affect the January and June forecasts, with little change anticipated for the February, March, April, and May forecasts. For more information, please contact [Danny Tappa \(daniel.tappa@usda.gov\)](mailto:danny.tappa@usda.gov)

April 2023: Idaho Water Supply Summary

Overview

Mother Nature did not get the memo that winter was supposed to come to an end. [March was colder than normal](#) across Idaho with well above normal precipitation south of the Clearwater Basin (Fig. 1). Precipitation amounts were so high last month that water supply conversations shifted from, “will we get out of drought?” to concerns about potential flooding. How quickly the snowpack melts this spring will determine the balance of having enough water or too much water. Cold temperatures across the state have delayed the runoff season; these delays are especially apparent in the Southern Snake basins, which typically begin their runoff season in mid-March. With [April forecasted to be cool and wet](#), increases in streamflow may continue to be delayed.

Large gains in the snowpack during March turned the tables for water supply. Streamflow forecasts are well above normal in southern Idaho, and in the Boise, Wood, Lost, Willow-Blackfoot-Portneuf, and Bear River basins. Water supply looks more than adequate across the state given the robust snowpack. Due to low reservoir storage in the Upper Snake River system, water supply could still be limited for some water users despite the improvements in this month’s streamflow forecasts.

Weather and drought outlooks

The first part of April is expected to be [warmer and potentially drier than normal](#) before returning to cool, wet conditions. In general, April is expected to be cooler and wetter than normal according to the [one month outlook](#) from NOAA’s Climate Prediction Center (CPC). Looking farther ahead, [cool temperatures](#) are favored this spring south of the Clearwater Basin. Northern Idaho may experience drier than normal conditions this spring; future precipitation conditions remain unknown elsewhere in the state. The CPC stated that [La Niña conditions ended in March](#), and predict El Niño-Southern Oscillation (ENSO) neutral conditions this spring and early summer.

[Drought status improved](#) across large swaths of Idaho. Drought category improvements occurred where this year’s snowpack is well above normal and reflect that northern Idaho is drier than central and southern Idaho. Currently, [31% of Idaho lands are in moderate drought \(D1\) with a portion of Lemhi County remaining in severe drought \(D2\)](#); the rest of the state is abnormally dry (DO). After multiple years of drought conditions, it will take time to fully recover. The [seasonal drought outlook](#) predicts drought will persist in the Panhandle but will improve across the rest of the state.

Snowpack

It was a very snowy March with records set at many SNOTEL stations [and snow courses!](#) The snowpack is near to well above normal across the entire state (Fig. 3). Basins south of the Clearwater have the highest snowpack (SWE) percentages compared to northern Idaho. Although March wasn't quite as wet in northern Idaho, all basins in that area finally reached normal snowpack conditions (94% to 101%). Snowpack ranges from 113% to 226% in the rest of the state as of April 1 (Fig. 3). Compared to median peak snowpack values in each basin, snowpack ranges from 84% to 168% (Fig. 4). Whatever metric you use, we can agree this has been a banner snow year for southern Idaho that will be talked about for years to come.

Cooler than normal temperatures across the state, especially south of the Snake River Plain, preserved the low and mid-elevation snowpack. Usually in March, the snowpack in the Southern Snake basins has begun melting but this year, it has just [kept growing](#). With warmer temperatures on the horizon, we should begin to see some melting occur at lower elevations. One way to track when the snowpack is ready to melt is to watch snow density increase as temperatures warm. As [snow density](#) reaches ~45%, it's a good indication the snowmelt runoff season has begun. These '[Snow to Flow](#)' graphs are helpful to see the past timing of snowmelt compared to that year's snowpack, the Northwest River Forecast Center (NWRFC) provide [river and flood forecasts](#), and the USGS site shows [real-time streamflow conditions](#).

Precipitation

In March, northern Idaho was much drier than the rest of the state. [Monthly precipitation](#) was 60 to 102% compared to the rest of the state, where precipitation was 134 to 203% of normal (Fig. 1). This pattern of drier conditions in northern Idaho has persisted from fall and through this winter. [Total water year precipitation](#) is 75 to 81% of normal in northern Idaho, near normal in the Salmon, West Central, and Upper Snake basins, and well above normal everywhere else (Fig. 2). The southeast portion of the state continued to be the wettest at ~142% of normal total water year precipitation.

Water supply and streamflow forecasts

Water supply conditions have turned around since last month with the very wet, cold March. All basins, apart from Upper Snake River water users, can expect sufficient water supply this irrigation season. This holds true especially if we have normal to above normal spring precipitation. Due to low reservoir carryover, water supply may still be limited for some water users in the Upper Snake River. However, the water supply picture for this important region has vastly improved over this winter.

April 1 [streamflow forecast](#) volumes increased significantly from last month (Fig. 5), reflecting the well above normal March precipitation and massive gains in the snowpack. The unusually large amounts of snow still lingering at the low and mid-elevations strongly influenced the rise in snowmelt runoff forecasts. Although [soil conditions remain dry](#) and may reduce snowmelt volume, there's enough water headed our way that dry soils likely won't play as big of a role this year as the previous two. The impacts of having large amounts of snow at these lower elevations in late winter will be determined by how quickly warm spring temperatures arrive and whether the nights are also warm. We would like to see a gradual snowmelt progression to avoid flooding.

For the primary forecast period, well above normal streamflow volumes are predicted in the Southern Snake, Boise, Wood, Lost, Willow-Blackfoot-Portneuf, and Bear River basins. Near normal streamflow is forecasted for the Upper Snake, Henrys Fork-Teton, Payette, Weiser, and Salmon basins. Streamflow is forecasted to be below normal in the Clearwater and Panhandle basins. To look at the range of possible streamflow volume outcomes, consult these [forecast graphics](#) for your basin of interest. Streamflow, snowpack, and precipitation data for each basin can be accessed [here](#) or on the NRCS interactive map [here](#).

[Reservoir storage is still below normal](#) across many parts of the state. This makes sense because inflow into reservoirs has been very low this winter. Streamflow for the October 1 to April 1 time period is well below normal. This reflects the multi-year drought, reduced groundwater and dry soil conditions as well as the colder than normal temperatures throughout this winter. However, once the snowpack begins melting, we will quickly see reservoirs begin to fill. In anticipation of all the runoff, [flood risk management operations](#) began on the Boise River system on April 3. [Reservoir storage in the Boise system](#) is 64% of capacity and the Payette system is at 61% of capacity.

On April 6, [reservoir storage in the Upper Snake River](#) system (above Milner Dam) is ~2.22 million acre-feet and is 55% full. The system is unlikely to fill this year although a rainy spring in combination with the above normal snowpack would help bring reservoir levels closer to normal in the upper system (Jackson Lake and Palisades Reservoirs). The NRCS forecast for [Snake River at Heise](#) during the April through September period is 110% of normal (4,020 KAF). The forecast increased by 380,000 acre-feet from last month. Downstream, the NWRFC forecast for [Snake River at Milner](#), is 103% of normal (6,371 KAF). Given current storage and streamflow forecasts, available water supply will likely be good but insufficient for all water users in this region. Continuation of wet conditions this spring would help alleviate water supply limitations for Upper Snake water users.

IDAHO SURFACE WATER SUPPLY INDEX (SWSI) April 1, 2023

The Surface Water Supply Index (SWSI) is a predictive indicator of surface water availability within a watershed for the spring and summer water use season. The index is calculated by combining pre-runoff reservoir storage (carryover) with forecasts of spring and summer streamflow. SWSI values are scaled from +4.0 (abundant supply) to -4.0 (extremely dry), with a value of zero indicating a median water supply as compared to historical occurrences. The SWSI analysis period is from 1991 to present.

SWSI values provide a more comprehensive outlook of water availability by combining streamflow forecasts and reservoir storage where appropriate. The SWSI index allows comparison of water availability between basins for drought or flood severity analysis. Threshold SWSI values have been determined for some basins to indicate the potential for agricultural irrigation water shortages.

BASIN or REGION	SWSI Value	Most Recent Year With Similar SWSI Value	Agricultural Water Supply Shortage May Occur When SWSI is Less Than
Spokane	-0.8	2019	NA
Clearwater	-1.5	2016	NA
Salmon	1.5	2012	NA
Weiser	1.0	2012	NA
Payette	1.0	2009	NA
Boise	2.0	2012	- 2.4
Big Wood above Hailey	2.5	1993	- 2.7
Big Wood	2.8	1999	0.6
Camas Creek nr Blaine	4.0	2006	NA

Owyhee	1.5	2005	- 2.1
Bear River	1.5	2021	- 3.9

SWSI SCALE, PERCENT CHANCE OF EXCEEDANCE, AND INTERPRETATION

NA=Not Available / Not Applicable; Note: The Percent Chance of Exceedance is an indicator of how often a range of SWSI values might be expected to occur. Each SWSI unit represents about 12% of the historical occurrences. As an example of interpreting the above scale, the SWSI can be expected to be greater than -3.0, 87% of the time and less than -3.0, 13% of the time. Half the time, the SWSI will be below and half the time above a value of zero. The interval between -1.5 and +1.5 described as "Near Normal Water Supply," represents three SWSI units and would be expected to occur about one-third (36%) of the time.

Panhandle Basins

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

Precipitation was below normal in March coming in at ~65% of normal (Fig. 1). The lack of precipitation last month did not improve water year total precipitation, which remains below normal at ~75% (Fig. 2). Below normal temperatures helped sustain snowpack conditions which are near normal across Panhandle basins (Fig. 3). A continuing trend this year is the discrepancy between high elevation and low elevation snowpack. [The snowpack at lower elevations \(below 5,000'\) is mostly above normal](#), while the [snowpack at higher elevations remains below normal at ~85%](#). The impacts of this abnormal distribution of snowpack will depend largely on springtime weather, but the timing and magnitude of snowmelt runoff could be affected. These basins typically reach peak snowpack sometime mid-April, and they are at ~80 to 90% of the typical peak SWE. [NOAA's Official 30-Day Outlook](#) predicts increased chances of above normal precipitation and below normal temperatures for April, which could delay when the snowmelt season begins.

Lakes in the Panhandle range from ~45 to 85% of normal storage: Lake Coeur d'Alene is at 45%, Lake Pend Oreille is at 78%, and Priest Lake at 84%. Streamflow forecasts for April through July range from ~85 to 95% of normal at the 50% exceedance level for the Panhandle basins.

Clearwater River Basin

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

The Clearwater received normal precipitation in March (Fig. 1) but there has been almost no improvement to water year total precipitation which is ~80% of normal (Fig. 2). The snowpack is near normal at 101% (Fig. 3). As of April 4, the Clearwater Basin reached normal peak SWE one week before the peak typically occurs. [NOAA's Official 30-Day Outlook](#) predicts increased chances of above normal precipitation and below normal temperatures in April which suggests this year's snowpack peak may reach above normal conditions. The CPC predicts [drought removal is likely](#); all of this bodes well for water supply in the Clearwater Basin.

Dworshak Reservoir is currently at 65% of its storage capacity, which is 95% of normal at this time of the year. Streamflow forecasts for the primary period range from ~90 to 95% of normal at the 50% exceedance level for the Clearwater River Basin.

Salmon River Basin

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

March precipitation was 171% of normal (Fig. 1). The wet month increased water year total precipitation from 84% to 98% of normal (Fig. 2). Snowpack increased during March and is 113% of normal as of April 1 (Fig. 3). The current snowpack is the highest we have observed since the winter of 2017, and conditions now exceed the [normal seasonal peak](#) snowpack, which is typically observed in mid-April. [Snowpack density](#) remains low for this time of year, which indicates widespread melt and runoff will be delayed this spring.

The Salmon River Basin streamflow forecasts are near normal and range from ~90 to 115%, except the Lemhi River (150%). Due to multi-year drought and lack of fall rains, [soil moisture](#) continues to be very low throughout the area which could decrease the amount of runoff. The Climate Prediction Center's [30-Day Outlook](#) for April predicts cooler temperatures and above normal precipitation will continue. Recreationalists with eyes on [peak flow timing](#) will want to keep a keen eye on the continued development of the snowpack, as well as forthcoming spring weather.

West Central Basins

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

Last month, we noted a change to more stormy weather in late February. The active weather pattern continued throughout March, resulting in monthly precipitation totals of ~170 to 200% of normal for March (Fig. 1). Water year total precipitation is now ~95 to 110% of normal (Fig. 2). Snowpack in the West Central basins is now significantly above normal and ranges from ~130 to 160% of normal on March 1 (Fig. 3). Currently, the snowpack has exceeded the normal seasonal peak in each of the [Weiser](#), [Boise](#), and [Payette](#) River basins. In the Boise River Basin, unusually high snowpack remains [below 6,000 ft elevation](#).

Reservoir storage in the Boise system (Anderson Ranch, Arrowrock and Lucky Peak combined) is 100% of normal, and storage in the Payette system is 91% of normal. Streamflow forecasts for the Boise River system range from ~120 to 165% of normal, and the Payette is ~100 to 120% of normal. The Climate Prediction Center's [30-Day Outlook](#) for April predicts cooler temperatures and above normal precipitation will continue. While the above normal snowpack brings much needed drought relief, it simultaneously carries the potential for spring flooding. If needed, NOAA's [Northwest River Forecast Center](#) provides a variety of products related to flood forecasting and awareness.

Wood & Lost River Basins

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

Monthly precipitation totals for March were well above normal across the Wood & Lost River basins. The Big & Little Wood, as well as the Big & Little Lost basins received ~210 to 230% of normal monthly precipitation, while the Birch-Medicine Lodge basins received 167% of normal (Fig. 1). Water year total precipitation is impressive across the area, and now ranges from ~115 to 135% of normal (Fig. 2). Basin snowpack is spectacular, with all basins between ~135 to 175% of normal for April 1 (Fig. 3). Current snowpack levels greatly exceed the normal seasonal peak snowpack ([Big Wood](#), [Little Wood](#), [Big Lost](#), [Little Lost](#), [Camas Creek](#)), and are the highest totals observed since 2017. [Snowpack density](#) remains low for this time of year, which is a strong indicator widespread melt and runoff will be delayed this spring.

April 1 reservoir storage is below the 30-year normal for Magic Reservoir (37%) and Mackay Reservoir (86%), while releases are being made from Little Wood Reservoir (51% of normal, 38% full) to make room for significant inflow there. Streamflow forecasts for the Wood and Lost basins are now significantly above normal and range from ~145 to 280% of normal. The median forecast for Camas Creek near Blaine is now 220 KAF (489% of normal!), which is more than enough to fill Magic Reservoir by itself. While the above normal snowpack brings much needed drought relief, it simultaneously carries the potential for spring flooding. If needed, NOAA's [Northwest River Forecast Center](#) provides a variety of products related to flood forecasting and awareness.

Upper Snake River Basins

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

Precipitation fell consistently throughout March as storm after storm hit the region. Monthly precipitation was well above normal for all Upper Snake basins (Fig. 1). Only Buffalo Fork, one of the easternmost sub-basins, received [below normal March precipitation](#). Water year total precipitation in the Upper Snake basins as of April 1 are well above normal; Henrys Fork-Teton is 117%, Snake River above Heise is 107%, and the Willow-Blackfoot-Portneuf is 144% of normal (Fig.2). Snowpack is well above normal in the Upper Snake River with basins ranging from 118 to 179% (Fig.3). [NOAA's Official 30-Day Outlook](#) predicts below normal temperatures to continue with no clear precipitation signal.

Storage is 87% of normal for the Upper Snake system. The Jackson Lake and Palisades reservoirs are 57% of normal (36% of capacity), and Henrys Fork-Teton reservoirs are 103% of normal (89% of capacity). With the roughly one million acre-feet deficit that began the winter, we will need well above normal streamflow to return to normal storage. [Median streamflow forecasts](#) for the region range from ~93 to 141% for the April to July runoff period. While the above normal snowpack brings much needed drought relief, it simultaneously carries the potential for spring flooding. If needed, NOAA's [Northwest River Forecast Center](#) provides a variety of products related to flood forecasting and awareness.

Southern Snake River Basins

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

March continued this winter's trend of above normal precipitation across the Southern Snake River basins. Monthly precipitation ranged between ~171 to 211%. Water year total precipitation continued to increase and is ~120 to 129% of normal across these basins. The snowpack is currently well above normal and ranges between ~135 to 226% of normal! Most SNOTEL sites in these basins surpassed the peak annual snowpack with little to no melting taking place yet. The deviation from normal is especially noticeable in the lower elevation areas that typically do not hold onto much snow this late into the season. The current snowpack is below normal density across the region. Less dense snow typically requires more energy input to produce snowmelt runoff, which suggests temperatures need to increase substantially before major runoff begins. However, with spring on our doorstep and the large amount of low-level snow we could see high runoff volumes soon. Comparable water years for each basin are: Owyhee [1982](#), [Bruneau 1983](#), [Salmon Falls 1983](#), [Goose Creek 1983](#), and [Raft 2011 & 2017](#).

Reservoir storage is below normal across the area, and current storage as a percent of normal is Oakley 71%, Wild Horse 91%, Lake Owyhee 50%, and Salmon Falls 53%. The current volumetric streamflow forecasts are well above normal for the 50% exceedance probability in each basin, they are: Owyhee 280%, Bruneau 195%, Salmon Falls 245%, and Goose Creek 237%. Water supply now looks sufficient in all of these basins.

Bear River Basin

April 1, 2023

Current Snowpack and Historic Range

Precipitation

WATER SUPPLY OUTLOOK

Monthly precipitation during March was 206%; more than double the amount of precipitation that typically falls in Bear River Basin at this time of year (Fig. 1). March precipitation at SNOTEL sites ranged from 150% to 255%. Water year total precipitation continues to be well above normal on April 1 for the Bear River Basin and is 142% of normal as of April 1 (Fig. 2). This winter, the snowpack in this basin exceeded the median snowpack peak prior to March 1 and is 148% of median peak as of April 1 (Fig. 4). The snowpack is 165% of normal and is at a [record high for most sites](#) with roughly a week left in the normal snow accumulation season (Fig.3). Moderate drought status has [improved to abnormally dry](#) across nearly all the basin, and [NOAA's Official 30-Day Outlook](#) forecasts above normal precipitation for the majority of Bear River Basin.

Reservoir storage for Bear Lake is 82% of normal (34% capacity) as of April 1. Streamflow forecasts in the region are predicting very high flows and range from ~140 to 345% for the April to July period. While the above normal snowpack brings much needed drought relief, it simultaneously carries the potential for spring flooding. If needed, NOAA's [Northwest River Forecast Center](#) provides a variety of products related to flood forecasting and awareness.

Normals based on 1991-2020 reference period: streamflow, snowpack, precipitation, & reservoir normals are medians.

1) 90% and 10% exceedance probabilities are actually 95% and 5%

2) Forecasts are for unimpaired flows. Actual flow will be dependent on management of upstream reservoirs and diversions

Reservoir Storage (KAF): End of March					Watershed Snowpack Analysis: April 1, 2023

Streamflow Adjustment List for All Forecasts Published in Idaho Water Supply Outlook Report: Streamflow forecasts are projections of runoff volumes that would occur without influences from upstream reservoirs or diversions. These values are referred to as natural, unregulated or adjusted flows. To make these adjustments, changes in reservoir storage, diversions, and inter-basin transfers are added or subtracted from the observed (actual) streamflow volumes. The following list documents the adjustments made for each forecast point. **(Revised Dec. 2018).**

Reservoir Capacity Definitions (Units in 1,000 Acre-Feet, KAF)

Different agencies use various definitions when reporting reservoir capacity and contents. Reservoir storage terms include dead, inactive, active, and surcharge storage. This table lists the volumes for each reservoir, and defines the storage volumes NRCS uses when reporting capacity and current reservoir storage. In most cases, NRCS reports usable storage which includes active and/or inactive storage. (Revised Feb. 2015)

Basin- Lake or Reservoir	Dead Storage	Inactive Storage	Active Storage	Surcharge Storage	NRCS Capacity	NRCS Capacity Includes
<u>Panhandle Region</u>						
Hungry Horse	39.73	---	3451.00	---	3451.0	Active

Montpelier	0.21	---	3.84	---	4.0	Dead + Active

Interpreting Water Supply Forecasts

Each month, five forecasts are issued for each forecast point and each forecast period. Unless otherwise specified, all streamflow forecasts are for streamflow volumes that would occur naturally without any upstream influences. Water users need to know what the different forecasts represent if they are to use the information correctly when making operational decisions. The following is an explanation of each of the forecasts.

90 Percent Chance of Exceedance Forecast. There is a 90 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 10 percent chance that the actual streamflow volume will be less than this forecast value.

70 Percent Chance of Exceedance Forecast. There is a 70 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 30 percent chance that the actual streamflow volume will be less than this forecast value.

50 Percent Chance of Exceedance Forecast. There is a 50 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 50 percent chance that the actual streamflow volume will be less than this forecast value. Generally, this forecast is the middle of the range of possible streamflow volumes that can be produced given current conditions.

30 Percent Chance of Exceedance Forecast. There is a 30 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 70 percent chance that the actual streamflow volume will be less than this forecast value.

10 Percent Chance of Exceedance Forecast. There is a 10 percent chance that the actual streamflow volume will exceed this forecast value, and there is a 90 percent chance that the actual streamflow volume will be less than this forecast value.

*Note: There is still a 20 percent chance that actual streamflow volumes will fall either below the 90 percent exceedance forecast or above the 10 percent exceedance forecast.

These forecasts represent the uncertainty inherent in making streamflow predictions. This uncertainty may include sources such as: unknown future weather conditions, uncertainties associated with the various prediction methodologies, and the spatial coverage of the data network in a given basin.

30-Year Median. The 30-year median streamflow for each forecast period is provided for comparison. The median is based on data from 1991-2020. The % MED column compares the 50% chance of exceedance forecast to the 30-year median streamflow; values above 100% denote when the 50% chance of exceedance forecast would be greater than the 30-year median streamflow.

AF - Acre-feet, forecasted volume of water are typically in thousands of acre-feet (KAF).

These forecasts are given to users to help make risk-based decisions. Users can select the forecast corresponding to the level of risk they are willing to accept in order to minimize the negative impacts of having more or less water than planned for.

To Decrease the Chance of Having Less Water than Planned for

A user might determine that making decisions based on a 50 percent chance of exceedance forecast is too much risk to take (there is still a 50% chance that the user will receive less than this amount). To reduce the risk of having less water than planned for, users can base their operational decisions on one of the forecasts with a greater chance of being exceeded such as the 90 or 70 percent exceedance forecasts.

To Decrease the Chance of Having More Water than Planned for

A user might determine that making decisions based on a 50 percent chance of exceedance forecast is too much risk to take (there is still a 50% chance that the user will receive more than this amount). To reduce the risk of having more water than planned for, users can base their operational decisions on one of the forecasts with a lesser chance of being exceeded such as the 30 or 10 percent exceedance forecasts.

Forecast use example:

Using the 50 Percent Exceedance Forecast. Using the example forecasts shown on the next page, there is a 50% chance that actual streamflow volume at the Henry's Fork near Ashton will be less than 280 KAF between June 1 and Sept. 30. There is also a 50% chance that actual streamflow volume will be greater than 280 KAF.

Using the 90 and 70 Percent Exceedance Forecasts. If an unexpected shortage of water could cause problems (such as irrigated agriculture), users might want to plan on receiving 245 KAF during Jun 1 through September 30 (from the 70 percent exceedance forecast). There is a 30% chance of receiving *less* than 245 KAF.

Alternatively, if users determine the risk of using the 70 percent exceedance forecast is too great, then they might plan on receiving 198 KAF (from the 90 percent exceedance forecast). There is 10% chance of receiving less than 72 KAF.

Using the 30 or 10 Percent Exceedance Forecasts. If an unexpected excess of water could cause problems (such as operating a flood control reservoir), users might plan on receiving 315 KAF between June 1 and

Sept. 30 (from the 30 percent exceedance forecast). There is a 30% chance of receiving *more* than 315 KAF.

Alternatively, if users determine the risk of using the 30 percent exceedance forecast is too great, then they might plan on receiving 360 KAF (from the 10 percent exceedance forecast). There is a 10% chance of receiving more than 360 KAF. Users could also choose a volume in between any of these values to reflect their desired risk level.

Upper Snake River Basin Streamflow Forecasts - June 1, 2015								
Forecast Point	Forecast Period	Forecast Exceedance Probabilities for Risk Assessment						
		---Drier---<---Projected Volume--->---Wetter---						
		90% (KAF)	70% (KAF)	50% (KAF)	% Avg	30% (KAF)	10% (KAF)	30yr Avg (KAF)
Henrys Fk nr Ashton	JUN-JUL	72	106	129	56	152	186	230
	JUN-SEP	198	245	280	68	315	360	410

Interpreting Snowpack Plots

Basin snowpack plots represent snow water equivalent indices using the average daily SNOTEL data¹ from several sites in or near individual basins. The solid red line (2015), which represents the current water year snowpack water content, can be compared to the normal dashed black line (Median) which is considered “normal”, as well as the SNOTEL observed historical snowpack range for each basin. This allows users to gather important information about the current year’s snowpack as well as the historical variability of snowpack in each basin.

The gray shaded area represents the interquartile range (also known as the “middle fifty”), which is the 25th to 75th percentiles of the historical daily snowpack data for each basin. Percentiles depict the value of the average snowpack below which the given percent of historical years fall. For example, the top part of the interquartile range (75th percentile) indicates that the snowpack index has been below this line for 75 percent of the period of record, whereas the reverse is true for the lower part of the interquartile range (25th percentile). This means 50 percent of the time the snowpack index is within the interquartile range (gray area) during the period of record.

¹ All data used for these plots come from daily SNOTEL data only and does not include snow course data (collected monthly), whereas the official basin snowpack percent of normal includes both SNOTEL and snow course data, potentially leading to slight discrepancies between plots and official basin percent of normal.

Current Snowpack and Historic Range
